CONTENTS

1 Executive Summary	32
2 Introduction	32
3 Data sources	33
3.1 Indicators	33
3.2 AIMS insitu samples	35
3.3 AIMS FLNTU samples	38
3.4 Remote sensing (BOM satellite)	40
3.5 eReefs coupled hydrodynamic – biogeochemical model	40
3.5.1 eReefs coupled model description and forcing	41
3.5.2 Assimilation system	42
3.5.3 Summary results	45
3.6 eReefs926	46
3.7 Thresholds	46
4 Exploratory data analysis	47
4.1 All data	47
4.2 Annual data	47
4.3 Monthly data	52
4.4 Spatial data	59
4.5 Comparison of data sources	68
5 Index metrics	80
5.1 Theoretical framework	80
5.1.1 Multivariate health indicators	80
5.1.2 Thresholds	80
5.1.3 Unifying indices	81
5.1.4 Hierarchical indices	81
5.2 Index sensitivity	86
5.3 Index explorations	91
5.3.1 Indices	91
5.3.2 Sources	112
5.3.3 Exploration of Measures	117
5.3.4 Measure/Site	120
5.4 Summary of recommendations	126
6 Hierarchical aggregations	127
6.1 Theoretical framework	127
6.1.1 Bootstrap aggregation	130
6.1.2 Beta approximation	131
6.1.3 Weights	131
6.1.4 Expert interventions	132
6.1.5 Scores and Grades	133
6.1.6 Certainty rating	134
6.1.7 Confidence intervals	139
6.2 Summary of adopted methodologies	140
6.3 Aggregation summaries	142
6.3.1 Site/Measure level	142
6.3.2 Site/Subindicator level	143
6.3.3 Site/Indicator level	144

6.3.4 Zone/Measure level	145
6.3.5 Zone/Subindicator	149
6.3.6 Zone/Indicator level	153
6.4 Aggregations to water body level	156
6.4.1 Water body/Measure level	156
6.4.2 Water body/Subindicator level	157
6.4.3 Water body/Indicator level	158
6.5 Aggregations to GBR level	159
6.5.1 GBR/Measure level	159
6.5.2 GBR/Subindicator level	161
6.5.3 GBR/Indicator level	163
6.6 Summary of recommendations	166
7 Exploration of focal areas	167
7.1 Simple aggregation	168
7.2 Ensemble Kalman Filter data assimilation	168
7.3 Gaussian Processes	169
7.4 Fixed Rank Kriging	171

LIST OF FIGURES

1	Great Barrier Reef Zones (Regions and Water Bodies).	34
2	Map of AIMS <i>in situ</i> samples.	36
3	Spatial and temporal distribution of AIMS insitu samples. Sites names follow Great Barrier Reef Marine Park Authority (GBRMPA) and sites are arranged north to south into the focal Regions. Blue shading of tiles denotes the number of surveys conducted in the year at each site.	37
4	Spatial and temporal distribution of AIMS FLNTU samples (Red: NTU, Green: Chlorophyll-a). Sites names follow Great Barrier Reef Marine Park Authority (GBRMPA) and sites are arranged north to south into the focal Regions.	39
5	Schematic showing eReefs coupled hydrodynamic biogeochemical model.	40
6	Schematic showing the evolution of the model ensemble over 6 assimilation cycles using the Ensemble Karman Filter (EnKF) system. The non-assimilating control run (black line) is capturing the gross cycle in the observations (blue stars), but errors remain that observations can constrain. At the initial time, all ensemble members, and the control run, have similar values. In the first five days the 108 members develop a spread, with the control run being different to the ensemble mean, but within the ensemble spread. At 5 days, the first state updating occurs. In the first 5 days there was only one observations, being above the ensemble mean. At day 5, a new state for the entire ensemble is calculated (the analysis being the mean of the updated ensemble) based on the mismatch between the ensemble members and observations. The updated state is closer to the model if the ensemble spread is small, or to the observations if they are dense with few errors. At day 5, because of the small positive mismatch, the ensemble spread is only slightly narrowed, and the mean increased. The ensemble members all restart from these new updated states. The next four analysis steps proceed much like the first. For the fifth analysis step, high density observation were available over the previous 5 days, so the analysis is weighted heavily toward the observations, and the model spread is constrained significantly. Looking at the error between the ensemble mean and the observations over the entire period we see that the data assimilation system has provided an improved estimate of the state (the mean of the ensemble) relative to the control run, and achieved this using the model that contains the processes we understand to describe system.	41
7	Example of the estimates of OC3M in the Cape York region on the 29 March 2016 using the 1 km GBR1 model and the NASA Aqua MODIS sensor: <i>in situ</i> chlorophyll concentration (left), the simulated OC3M (centre) and the NASA observed OC3M (right).	44
8	Comparison of the non-assimilating (blue) and assimilating (pink) runs at the MMP sites. The instantaneous state root mean square error at the 14 MMP sites (top). The approximate error in the observations is 0.2 mg m^{-3} . At Double Cone Island in the Whitsundays (off Airlie Beach), a time-series of the observations (black dots) and simulations is shown for the whole simulations (centre) and the a 1 year period (bottom).	45
9	Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.	48
10	Observed (logarithmic axis with violin plot overlay) TSS data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.	49

- 11 Observed (logarithmic axis with violin plot overlay) Secchi depth data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 50
- 12 Observed (logarithmic axis with violin plot overlay) NOx data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) eReefs and c) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 51
- 13 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU. Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 53
- 14 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Open Coastal Zone from a) Satellite, b) eReefs. Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 54
- 15 Observed (logarithmic axis with violin plot overlay) TSS data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU. Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 55
- 16 Observed (logarithmic axis with violin plot overlay) TSS data for the Wet Tropics Open Coastal Zone from a) Satellite, b) eReefs. Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 56
- 17 Observed (logarithmic axis with violin plot overlay) Secchi depth data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) Satellite and c) eReefs. Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 57
- 18 Observed (logarithmic axis with violin plot overlay) Secchi depth data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) eReefs c) eReefs926. Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 58
- 19 Spatial distribution of observed a) AIMS insitu, b) Satellite, c) eReefs and d) eReefs926 Chlorophyll-a (2009–2016) for the Wet Tropics Open Coastal Zone. 60

20	Spatial distribution of observed a) AIMS insitu, b) Satellite, c) eReefs and d) eReefs926 TSS (2009–2016) for the Wet Tropics Open Coastal Zone.	61
21	Spatial distribution of observed a) AIMS insitu, b) Satellite, c) eReefs and d) eReefs926 Secchi depth (2009–2016) for the Wet Tropics Open Coastal Zone.	62
22	Spatial distribution of observed a) AIMS insitu, b) eReefs and c) eReefs926 NOx (2009–2016) for the Wet Tropics Open Coastal Zone.	63
23	Spatial distribution of observed a) AIMS insitu, b) Satellite, c) eReefs and d) eReefs926 Chlorophyll-a (2009–2016) for the Dry Tropics Midshelf Zone.	64
24	Spatial distribution of observed a) AIMS insitu, b) Satellite, c) eReefs and d) eReefs926 TSS (2009–2016) for the Dry Tropics Midshelf Zone.	65
25	Spatial distribution of observed a) AIMS insitu, b) Satellite, c) eReefs and d) eReefs926 Secchi depth (2009–2016) for the Dry Tropics Midshelf Zone.	66
26	Spatial distribution of observed a) AIMS insitu, b) eReefs and c) eReefs926 NOx (2009–2016) for the Dry Tropics Midshelf Zone.	67
27	Location of Satellite cells within 5km of AIMS niskin samples. Panel borders represent water bodies (Red: Enclosed Coastal, Green: Open Coastal, Blue: Midshelf).	74
28	Location of eReefs cells within 5km of AIMS niskin samples. Panel borders represent water bodies (Red: Enclosed Coastal, Green: Open Coastal, Blue: Midshelf).	75
29	Temporal patterns in Chlorophyll-a within 5km of each AIMS MMP sampling site for eReefs, Satellite and AIMS insitu and FLNTU logger sources. Horizontal dashed line represents the guideline value. Title backgrounds represent water bodies (Red: Enclosed Coastal, Green: Open Coastal, Blue: Midshelf).	76
30	Temporal patterns in TSS within 5km of each AIMS MMP sampling site for eReefs, Satellite and AIMS insitu and FLNTU logger sources. Horizontal dashed line represents the guideline value. Title backgrounds represent water bodies (Red: Enclosed Coastal, Green: Open Coastal, Blue: Midshelf).	77
31	Temporal patterns in Secchi Depth within 5km of each AIMS MMP sampling site for eReefs, Satellite and AIMS insitu and FLNTU logger sources. Horizontal dashed line represents the guideline value. Title backgrounds represent water bodies (Red: Enclosed Coastal, Green: Open Coastal, Blue: Midshelf).	78
32	Temporal patterns in NOx within 5km of each AIMS MMP sampling site for eReefs, Satellite and AIMS insitu and FLNTU logger sources. Horizontal dashed line represents the guideline value. Title backgrounds represent water bodies (Red: Enclosed Coastal, Green: Open Coastal, Blue: Midshelf).	79
33	Simulated data and associated indices for threshold of 0.1 and very large sample sizes (R=1000). Samples represent high variability relative to threshold.	86
34	Simulated data and associated indices for threshold of 10 and very large sample sizes (R=1000). .	87
35	Simulated data and associated indices for threshold of 100 and very large sample sizes (R=1000). .	88
36	Simulated data and associated indices for threshold of 1 and large sample sizes (R=100).	88
37	Simulated data and associated indices for threshold of 10 and small sample sizes (R=10).	89
38	Temporal distribution of AIMS insitu Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	93

39	Temporal distribution of AIMS FLNTU Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	94
40	Temporal distribution of Satellite Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	95
41	Temporal distribution of eReefs Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	96
42	Temporal distribution of eReefs926 Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	97
43	Spatial distribution of AIMS in situ Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	98
44	Spatial distribution of Satellite Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	99
45	Spatial distribution of eReefs Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	100
46	Spatial distribution of eReefs926 Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	101
47	Spatial distribution of AIMS insitu Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Dry Tropics Midshelf zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	102
48	Spatial distribution of AIMS FLNTU Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Dry Tropics Midshelf zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	103
49	Spatial distribution of Satellite Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Dry Tropics Midshelf zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	104

50	Spatial distribution of eReefs Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Dry Tropics Midshelf zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	105
51	Spatial distribution of eReefs926 Chlorophyll-a a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Dry Tropics Midshelf zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	106
52	Time series of annually aggregated Binary, fsMAMP and fsMAMP4 index formulations for AIMS insitu Chlorophyll-a across each of the Regions and Water bodies. The blue vertical bar spans from mid 2009 to mid 2011.	107
53	Time series of annually aggregated Binary, fsMAMP and fsMAMP4 index formulations for AIMS FLNTU Chlorophyll-a across each of the Regions and Water bodies. The blue vertical bar spans from mid 2009 to mid 2011.	108
54	Time series of annually aggregated Binary, fsMAMP and fsMAMP4 index formulations for Satellite Chlorophyll-a across each of the Regions and Water bodies. The blue vertical bar spans from mid 2009 to mid 2011.	109
55	Time series of annually aggregated Binary, fsMAMP and fsMAMP4 index formulations for eReefs Chlorophyll-a across each of the Regions and Water bodies. The blue vertical bar spans from mid 2009 to mid 2011.	110
56	Time series of annually aggregated Binary, fsMAMP and fsMAMP4 index formulations for eReefs926 Chlorophyll-a across each of the Regions and Water bodies. The blue vertical bar spans from mid 2009 to mid 2011.	111
57	Time series of fsMAMP Chlorophyll-a index scores by zone for each data source. The blue vertical bar spans from mid 2009 to mid 2011.	113
58	Time series of fsMAMP TSS index scores by zone for each data source. The blue vertical bar spans from mid 2009 to mid 2011.	114
59	Time series of fsMAMP Secchi depth index scores by zone for each data source. The blue vertical bar spans from mid 2009 to mid 2011.	115
60	Time series of fsMAMP NOx index scores by zone for each data source. The blue vertical bar spans from mid 2009 to mid 2011.	116
61	Time series of eReefs fsMAMP index scores by zone. The blue vertical bar spans from mid 2009 to mid 2011.	117
62	Time series of eReefs fsMAMP Measure Index Scores by zone. The blue vertical bar spans from mid 2009 to mid 2011.	119
63	Spatio-temporal Satellite fsMAMP Chlorophyll-a index scores.	120
64	Spatio-temporal Satellite fsMAMP TSS index scores.	121
65	Spatio-temporal Satellite fsMAMP Secchi depth index scores.	122
66	Spatio-temporal eReefs fsMAMP Chlorophyll-a index scores.	123
67	Spatio-temporal eReefs fsMAMP TSS index scores.	123
68	Spatio-temporal eReefs fsMAMP Secchi depth index scores.	124
69	Spatio-temporal eReefs fsMAMP NOx index scores.	124
70	Spatio-temporal eReefs926 fsMAMP Chlorophyll-a index scores.	124
71	Spatio-temporal eReefs926 fsMAMP TSS index scores.	125
72	Spatio-temporal eReefs926 fsMAMP Secchi depth index scores.	125
73	Spatio-temporal eReefs926 fsMAMP NOx index scores.	125
74	Temporal, measure and spatial aggregation hierarchy	127

75	Schematic illustrating four possible aggregation routines through the combination of Temporal (Daily, Seasonal and Annual), Spatial (Site, Zone) and Measure (Measure, Sub-indicator, Indicator) nodes of the triple hierarchical aggregation routine associated with the GBR Report Card. Aggregation directions between nodes are signified by arrows and the main aggregation pathway through the routines is illustrated by the green polygon.	129
76	Illustration of Bootstrapped aggregation of three distributions. Simple summary statistics (mean, variance and 95% confidence interval presented for each distribution).	130
77	Beta probability densities	132
78	Score to grade conversion control charts. In each case, the scale along the base defines the grade boundaries.	133
79	Schematic illustrating the major steps of the GBR Report Card. In this fabricated example, there are three Measures (Red, Green and Blue). Each of the Blue and Green Measures are represented by a single discrete observation, whereas the Red Measure is represented by a large collection of observations. Expert option intervened to lower the blue Measure distribution from observed values at 0.8 to 0.6.	141
80	Spatio-temporal patterns in eReefs fsMAMP Chlorophyll-a index grades (Uniform grade type control chart applied).	142
81	Spatio-temporal patterns in eReefs fsMAMP Secchi Depth index grades (Uniform grade type control chart applied).	143
82	Spatio-temporal patterns in eReefs fsMAMP Productivity index grades (Uniform grade type control chart applied).	143
83	Spatio-temporal patterns in eReefs fsMAMP Water Clarity index grades (Uniform grade type control chart applied).	144
84	Spatio-temporal patterns in eReefs fsMAMP Water Quality index grades (Uniform grade type control chart applied).	144
85	Time series of fsMAMP measures (Chlorophyll-a and Secchi Depth) index scores by zone. The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	146
86	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Chlorophyll-a index grades (Uniform grade type control chart applied).	147
87	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Secchi Depth index grades (Uniform grade type control chart applied).	147
88	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Chlorophyll-a index grades (Uniform grade type control chart applied).	148
89	Time series of fsMAMP Productivity and Water Clarity index scores by zone. The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	150
90	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Productivity index grades (Uniform grade type control chart applied).	151
91	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Water Clarity index grades (Uniform grade type control chart applied).	151
92	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Subindicator index grades (Uniform grade type control chart applied).	152
93	Time series of fsMAMP Water Quality index scores by zone. The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	154
94	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Productivity index grades (Uniform grade type control chart applied).	155
95	Simplified (Zone mean) eReefs spatio-temporal fsMAMP indicator index grades (Uniform grade type control chart applied).	155

96	Time series of fsMAMP Measure index scores by water body (aggregated over management region weighted by area). The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	156
97	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Measurement index grades (Uniform grade type control chart applied).	157
98	Time series of fsMAMP Subindicator index scores by water body (aggregated over management region weighted by area). The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	157
99	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Subindicator index grades (Uniform grade type control chart applied).	158
100	Time series of fsMAMP Indicator index scores by water body (aggregated over management region weighted by area). The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	158
101	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Indicator index grades (Uniform grade type control chart applied).	159
102	Time series of fsMAMP Measure index scores by GBR (aggregated over management region weighted by area). The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	160
103	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Measurement index grades (Uniform grade type control chart applied).	161
104	Time series of fsMAMP Subindicator index scores by GBR (aggregated over management region weighted by area). The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	162
105	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Subindicator index grades (Uniform grade type control chart applied).	163
106	Time series of fsMAMP Indicator index scores by GBR (aggregated over management region weighted by area). The blue vertical bar spans from mid 2009 to mid 2011. Faint colored horizontal bands represent Uniform grade ranges.	164
107	Simplified (Zone mean) eReefs spatio-temporal fsMAMP Indicator index grades (Uniform grade type control chart applied).	165
108	Spatial distribution of eReefs observation locations within 5km of the Yongala AIMS MMP niskin sampling location (point with red outline). Observations represent a) Chlorophyll-a values and associated b) fsMAMP indices and c) Grades (Uniform control chart) for 25/03/2015.	167
109	Yongala focal area aggregated a) Chlorophyll-a values and associated b) fsMAMP indices and c) Grades (Uniform control chart) for 25/03/2015.	168
110	Illustration of data assimilation via squared exponential Gaussian process applied to a single dimension (Latitude) for the 25/03/2015 Yongala focal area a) Raw Chlorophyll-a values and b-e) different Gaussian Process parameters.	171
111	Illustration of data assimilation via Fixed Rank Kriging applied to spatial data for the 25/03/2015 Yongala focal area a) Raw Chlorophyll-a values (AIMS niskin: red symbol border, eReefs: black symbol border), b) discretization of the spatial domain into a regular hexagonal grid and varying footprints (support) for AIMS niskin (blue) and eReefs (red), d) Matern basis functions of two resolutions, d) predicted values and associated e) fsMAMP indices and f) Grades (Uniform control chart) for 25/03/2015.	172

- C1 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 183
- C2 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 184
- C3 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 185
- C4 Observed (logarithmic axis with violin plot overlay) NOx data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 186
- C5 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Cape York Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 187
- C6 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Cape York Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 188
- C7 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Cape York Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 189

- C8 Observed (logarithmic axis with violin plot overlay) NOx data for the Cape York Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 190
- C9 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Cape York Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 191
- C10 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Cape York Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 192
- C11 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Cape York Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 193
- C12 Observed (logarithmic axis with violin plot overlay) NOx data for the Cape York Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 194
- C13 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Cape York Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 195
- C14 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Cape York Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 196

- C15 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Cape York Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 197
- C16 Observed (logarithmic axis with violin plot overlay) NOx data for the Cape York Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 198
- C17 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 199
- C18 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Wet Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 200
- C19 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Wet Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 202
- C20 Observed (logarithmic axis with violin plot overlay) NOx data for the Wet Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 203
- C21 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 204

- C29 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 212
- C30 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Wet Tropics Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 213
- C31 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Wet Tropics Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 214
- C32 Observed (logarithmic axis with violin plot overlay) NOx data for the Wet Tropics Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 215
- C33 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Dry Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 216
- C34 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Dry Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 217
- C35 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Dry Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 218

- C36 Observed (logarithmic axis with violin plot overlay) NOx data for the Dry Tropics Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: x4,/4; 30% shade: x2,/2) above and below threshold respectively.

C37 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Dry Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: x4,/4; 30% shade: x2,/2) above and below threshold respectively. 219

C38 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Dry Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: x4,/4; 30% shade: x2,/2) above and below threshold respectively. 220

C39 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Dry Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: x4,/4; 30% shade: x2,/2) above and below threshold respectively. 221

C40 Observed (logarithmic axis with violin plot overlay) NOx data for the Dry Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: x4,/4; 30% shade: x2,/2) above and below threshold respectively. 222

C41 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Dry Tropics Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: x4,/4; 30% shade: x2,/2) above and below threshold respectively. 223

C42 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Dry Tropics Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: x4,/4; 30% shade: x2,/2) above and below threshold respectively. 224

- C57 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Mackay Whitsunday Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 241
- C58 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Mackay Whitsunday Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 242
- C59 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Mackay Whitsunday Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 243
- C60 Observed (logarithmic axis with violin plot overlay) NOx data for the Mackay Whitsunday Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 244
- C61 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Mackay Whitsunday Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 245
- C62 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Mackay Whitsunday Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 246
- C63 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Mackay Whitsunday Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 247

- C64 Observed (logarithmic axis with violin plot overlay) NOx data for the Mackay Whitsunday Off-shore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 248
- C65 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Fitzroy Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 249
- C66 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Fitzroy Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 250
- C67 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Fitzroy Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 251
- C68 Observed (logarithmic axis with violin plot overlay) NOx data for the Fitzroy Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 252
- C69 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Fitzroy Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 253
- C70 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Fitzroy Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 254

- C71 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Fitzroy Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 255
- C72 Observed (logarithmic axis with violin plot overlay) NOx data for the Fitzroy Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 256
- C73 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Fitzroy Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 257
- C74 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Fitzroy Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 258
- C75 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Fitzroy Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 259
- C76 Observed (logarithmic axis with violin plot overlay) NOx data for the Fitzroy Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 260
- C77 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Fitzroy Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively. 261

C92 Observed (logarithmic axis with violin plot overlay) NOx data for the Burnett Mary Midshelf Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.	276
C93 Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Burnett Mary Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.	277
C94 Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Burnett Mary Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.	278
C95 Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Burnett Mary Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.	279
C96 Observed (logarithmic axis with violin plot overlay) NOx data for the Burnett Mary Offshore Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.	280
C97 Temporal distribution of AIMS insitu Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	281
C98 Spatial distribution of AIMS in situ Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	282

C99 Temporal distribution of AIMS FLNTU Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	283
C100 Temporal distribution of Satellite Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	284
C101 Spatial distribution of Satellite Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	285
C102 Temporal distribution of eReefs Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	286
C103 Spatial distribution of eReefs Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	287
C104 Temporal distribution of eReefs926 Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	288
C105 Spatial distribution of eReefs926 Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	289
C106 Temporal distribution of AIMS insitu Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	290
C107 Spatial distribution of AIMS in situ Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	291
C108 Temporal distribution of AIMS FLNTU Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	292

C109 Temporal distribution of Satellite Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	293
C110 Spatial distribution of Satellite Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	294
C111 Temporal distribution of eReefs Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	295
C112 Spatial distribution of eReefs Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	296
C113 Temporal distribution of eReefs926 Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	297
C114 Spatial distribution of eReefs926 Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	298
C115 Temporal distribution of AIMS insitu NOx a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	299
C116 Spatial distribution of AIMS in situ NOx a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	300
C117 Temporal distribution of eReefs NOx a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	301
C118 Spatial distribution of eReefs NOx a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	302

C119 Temporal distribution of eReefs926 NOx a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	303
C120 Spatial distribution of eReefs926 NOx a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	304
C121 Temporal distribution of AIMS insitu Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	306
C122 Spatial distribution of AIMS in situ Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	307
C123 Temporal distribution of AIMS FLNTU Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	308
C124 Temporal distribution of Satellite Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	309
C125 Spatial distribution of Satellite Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	310
C126 Temporal distribution of eReefs Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	311
C127 Spatial distribution of eReefs Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	312
C128 Temporal distribution of eReefs926 Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	313

C129 Spatial distribution of eReefs926 Total Suspended Solids a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	314
C130 Temporal distribution of AIMS insitu Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	315
C131 Spatial distribution of AIMS in situ Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	316
C132 Temporal distribution of Satellite Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	317
C133 Spatial distribution of Satellite Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMP4.	318
C134 Temporal distribution of eReefs Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.	319
C135 Spatial distribution of eReefs Secchi Depth a) samples and associated b) Binary, c) fsMAMP and d) fsMAMP4 index formulations for the Wet Tropics Open Coastal zone. I. EXECUTIVE SUMMARY**2. INTRODUCTION**

3. DATA SOURCES

Report cards are typically compiled and communicated annually. However, the time window that constitutes a year differs from report card to report card. Many environmental report cards communicate on data collected within a financial year. This schedule provides a reporting window that is consistent with other management and governmental considerations. Others use a time window that naturally aligns with the cycle of some major underlying environmental gradient - such as wet/dry season. For this project, we are adopting using the same water year (1st Oct – 31 Sept) definition as the AIMS inshore Water Quality Marine Monitoring Program (Lønborg et al., 2016).

The Great Barrier Reef Marine Park (GBR) spans nearly 14° of latitude and covers approximately 344,400km².

- spanning multiple jurisdictions/pressures as well as distance offshore - more useful to partition the GBR into smaller more homogeneous zones representing combinations of region and water body. - Six regions (Cape York, Wet Tropics, Dry Tropics, Mackay Whitsunday, Fitzroy and Burnett Mary) - Four water bodies (Enclosed Coastal, Open Coastal, Midshelf and Offshore) - define each...

3.1 Indicators

One of the biggest challenges of report card development is the selection of appropriate indicators from amongst a potentially very large candidate pool. Since the outcomes, conclusions and implications are all dependent on the indicators selected, the selection process is one of the most influential steps and has justifiably received a great deal of attention.

As part of their ecosystem report card framework, Harwell et al. (1999) urged that the alignment of scientific information with societal goals and objectives should be the guiding principle of indicator selection. In their framework, clearly articulated societal goals and objectives (a combination of societal values and scientific knowledge, such as restored and sustainable wetland system) are translated into Essential Ecosystem Characteristics (EECs)

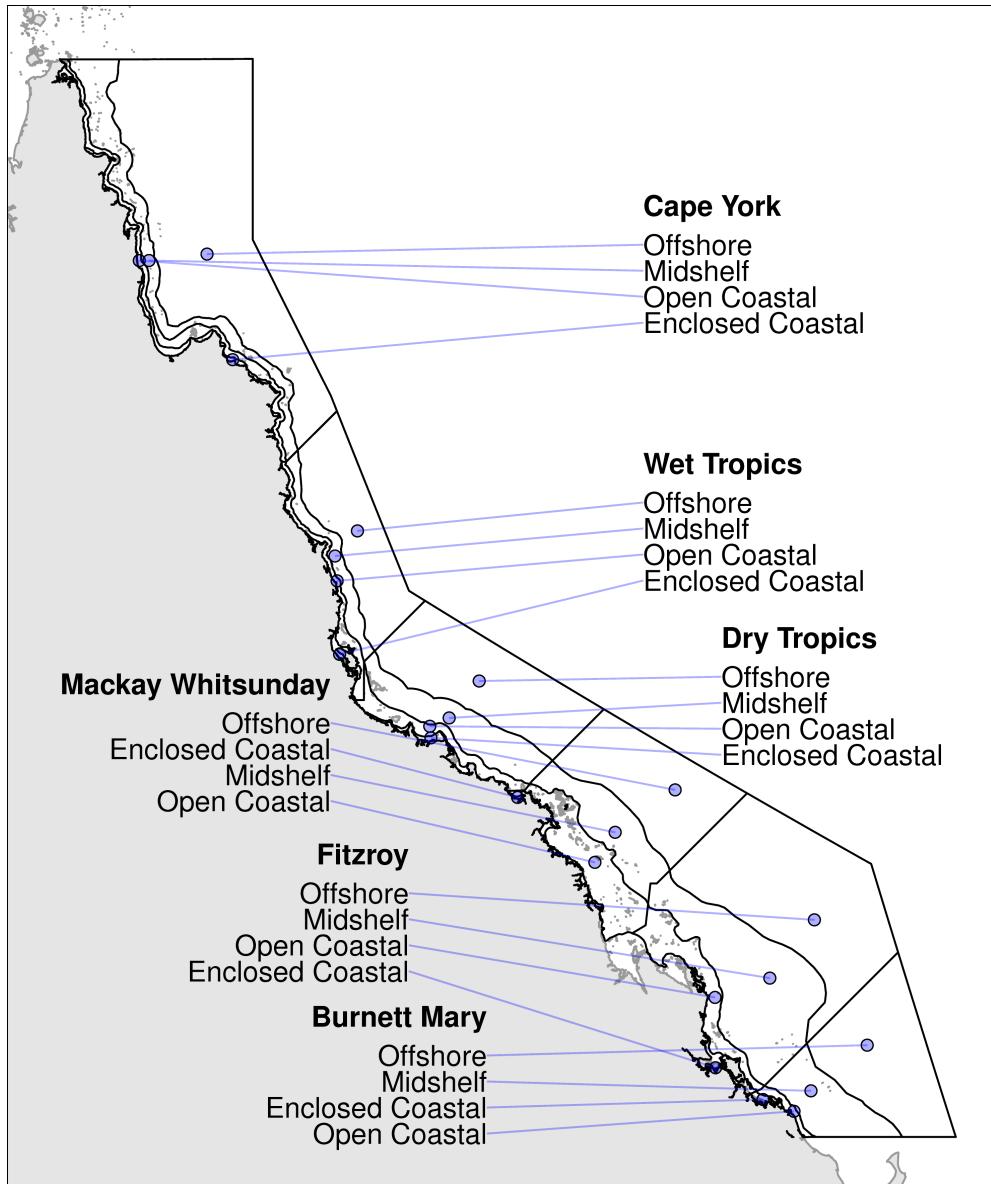

Figure 1: Great Barrier Reef Zones (Regions and Water Bodies).

that represent a set of generic attributes that further refine the broad goals (such as water quality, sediment quality, habitat quality, ecological processes). The EEC's are then further translated into a set of scientific informed indicators that are measured or monitored to indicate the status of trends or states associated with the EEC's.

There have since been numerous studies that have focused on providing more formal, objective criterion for indicator selection (Dauvin et al., 2008; Emerson et al., 2012; Flint et al., 2012; James et al., 2012). Whilst the specifics vary, most can be broadly encapsulated by a Dauvin et al. (2008)'s contextual implementation of the Doran (1981)'s SMART (Simple, Measurable, Achievable, Realistic, and Time limited) principle. A 'good' indicator should be representative, easily interpreted, broadly comparable, sensitive to change and have a reference or guideline value. To be 'useful', an indicator must be approved by international consensus, be well grounded and documented, have a reasonable cost/benefit ratio and have adequate historical and on-going spatial-temporal coverage. Flint et al. (2012) and James et al. (2012) further developed numerical scoring systems to help evaluate indicators objectively. Nevertheless, (Neary, 2012) warned against the potential to manipulate an index by saturating with inappropriate or biased indicators and whilst recommending that an index comprise of at least seven indicators, they did advocate that the type of indicator is more important than the number of indicators.

Since final outcomes are likely to be highly influenced by indicator choice, the robustness and sensitivity of both indicators and final outcomes to changes in ecosystem health should be understood if not formally investigated as part of the indicator selection process (Dobbie and Dail, 2013). Sensitivity analyses can involve:

- simulating changes in the underlying data of different magnitudes and estimating the resulting sensitivity (percentage or probability of change) expressed by the indicator
- estimating the effect of past perturbations on the indicator hindcasted from on historical data

As stressed above, indicators should align intimately with report card objectives. Yet in the more broad ecosystem report card frameworks, such indicators are often too general to be measurable. Therefore, in such cases, the indicators are further sub-divided into progressively more specific measures. For example, an indicator of water quality might comprise sub-indicators of nutrients, metals and physico-chemistry which in turn might be represented by more specific measures such as total nitrogen, mercury, dissolved oxygen, pH etc.

The resulting design is a hierarchical structure in which sub-indicators (etc) are nested within indicators and spatial scales are nested from entire regions, sub-regions or zones down to individual sites or sampling units. One of the strengths of such a hierarchical report card framework is that the inherent inbuilt redundancy allows for the addition, deletion or exchange of finer scale items (sites and actual measured variables) with minimum disruption to the actual report indicators. That is, the indicator is relatively robust to some degree of internal makeup. Furthermore, by abstracting away the fine details of an indicator, similar indicators from different report cards (each potentially comprising different sampling designs) are more directly comparable. For example, in different report cards that include water quality, a water quality indicator of 'water clarity' might comprise different Measures (e.g. suspended solids, NTU, Secchi depth etc) collected from different sources (e.g. satellite, in situ loggers or hand samples), yet provided each of these water clarity indicators are well calibrated, it should be possible to compare state and trend across the report cards.

Table 3: Water Quality Measure hierarchy specifying which Measures contribute to which Subindicators and which Subindicators contribute to which Indicators.

Indicator	Subindicator	Measure	Label	Units
Water Quality	Productivity	chl	Chlorophyll	$\mu\text{g L}^{-1}$
Water Quality	Water Clarity	nap	TSS	mg L^{-1}
Water Quality	Water Clarity	ntu	NTU	NTU
Water Quality	Water Clarity	sd	Secchi	m
Water Quality	Nutrients	NOx	NOx	$\mu\text{g L}^{-1}$

3.2 AIMS insitu samples

The AIMS component of MMP inshore water quality monitoring sampling program has been designed to quantify spatial and temporal patterns in inshore water quality, particularly in the context of catchment loads. Details of the sampling design are outlined in (Lønborg et al., 2016). From 2006–2014, AIMS visited 20 sites, three times per year (roughly corresponding to wet, early and late dry seasons), see Figures 2 and 3. The sites were largely

selected along approximate north-south transects proximal to major rivers so as to provide samples along an expected water quality gradients (exposure to runoff). Following a review in 2014, the design was modified to intensify the spatial (32 sites) and temporal (typically between 5 and 10 samples per year) coverage of the sampling program. In particular, additional sampling effort was applied around three priority focal areas (Russell-Mulgrave, Tully and Burdekin).

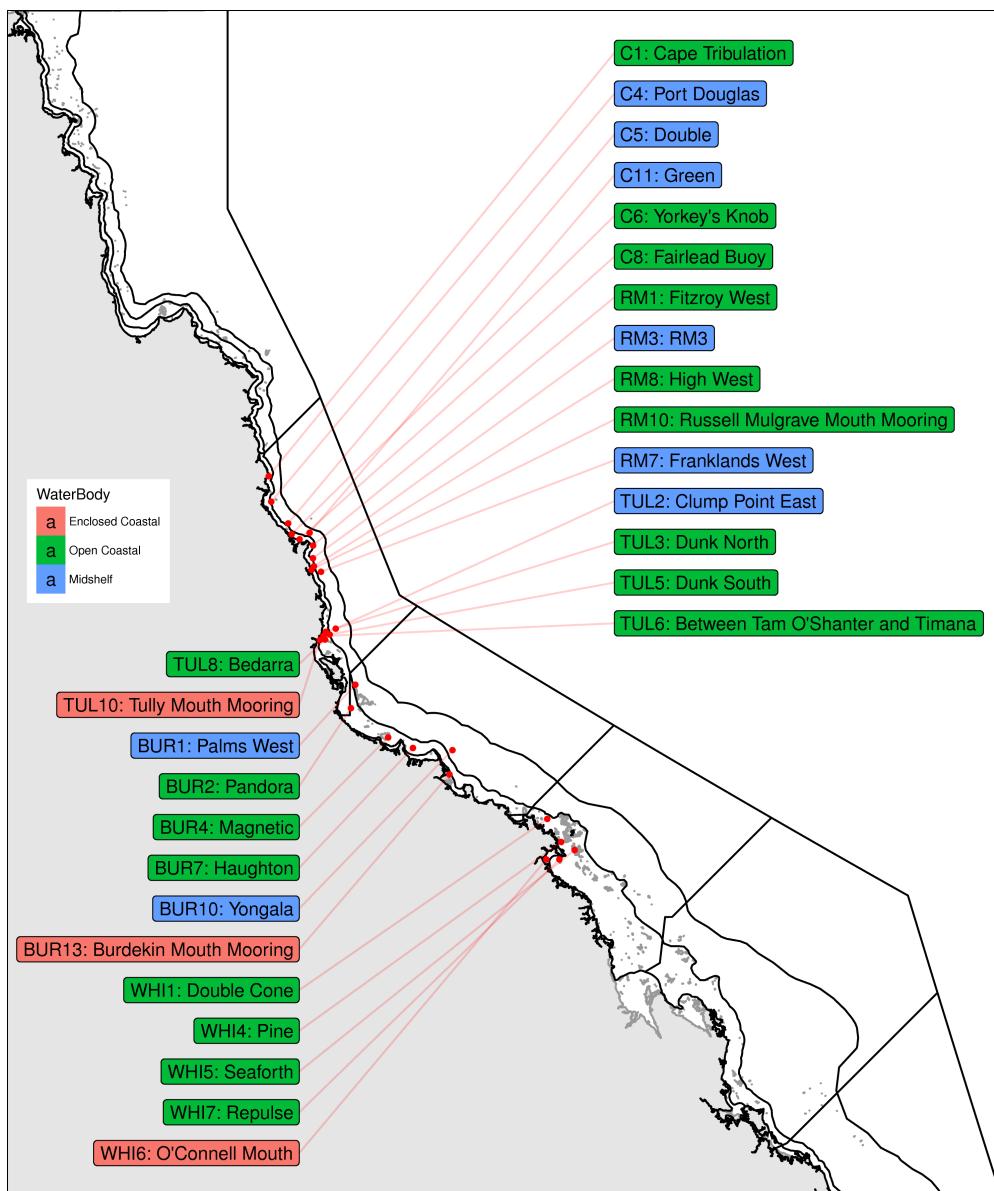

Figure 2: Map of AIMS in situ samples.

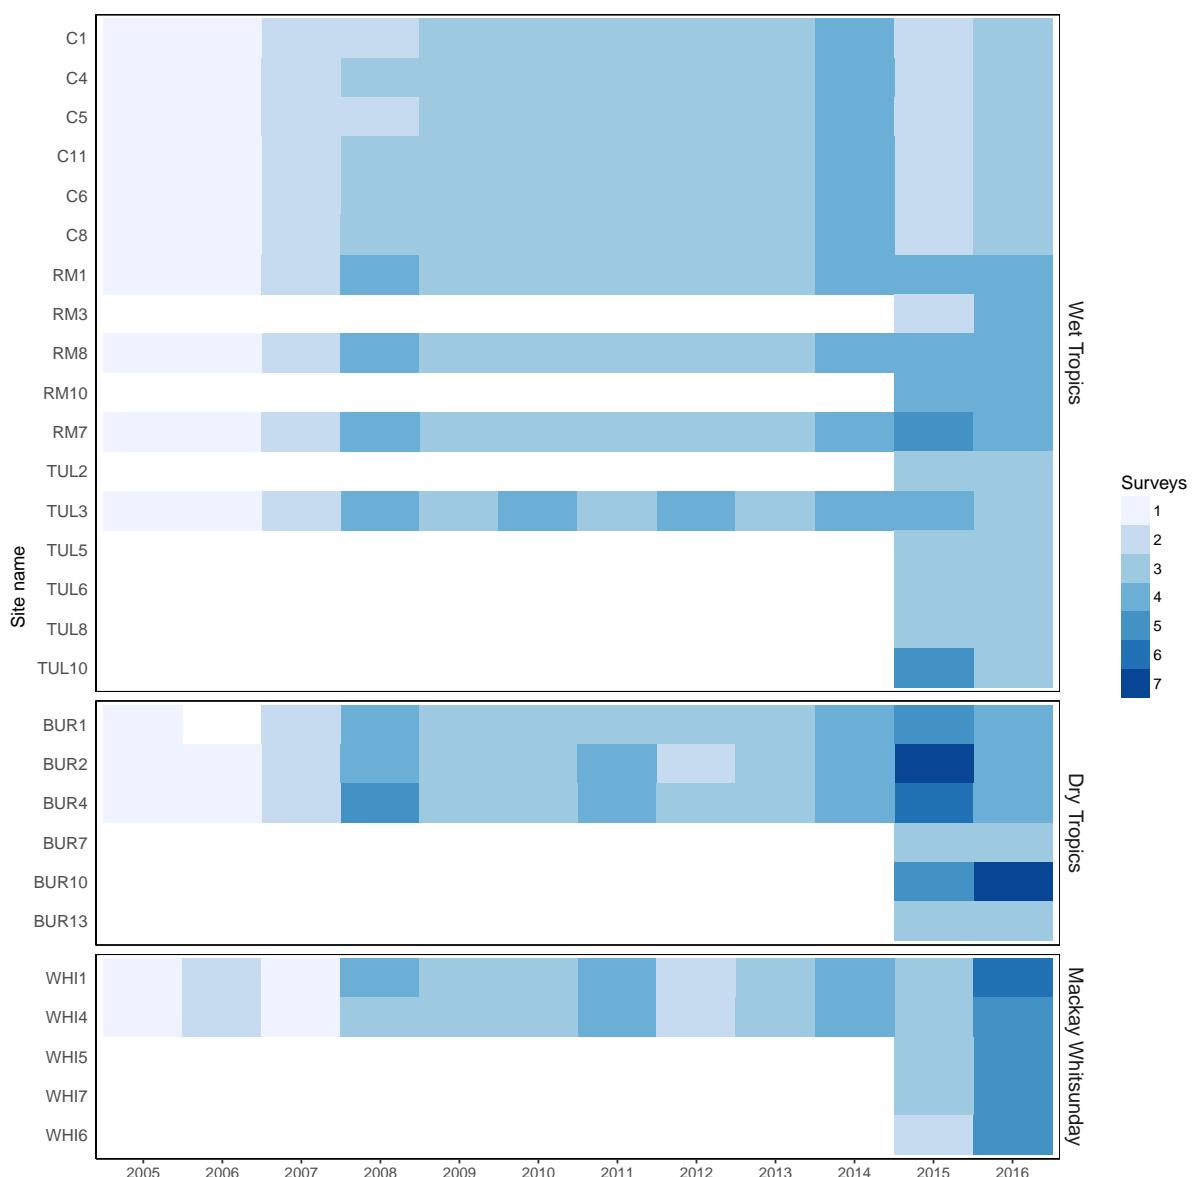

Figure 3: Spatial and temporal distribution of AIMS insitu samples. Sites names follow Great Barrier Reef Marine Park Authority (GBRMPA) and sites are arranged north to south into the focal Regions. Blue shading of tiles denotes the number of surveys conducted in the year at each site.

Table 4: Measures collected in AIMS MMP insitu inshore water quality monitoring program. NOx is the sum of NO₂ and NO₃. Data used are annual means of depth weighted averages per site.

Measure	Variable	Description	Abbreviation	Conversion	Units
Chlorophyll-a	DRIFTCHL_UGPERL.wm	Chlorophyll-a ($\mu\text{g/L}$)	chl	x1	$\mu\text{g L}^{-1}$
Total Suspended Solids	TSS_MGPERL.wm	Suspended solids (mg/L)	nap	x1	mg L^{-1}
Secchi Depth	SECCHI_DEPTH.wm	Secchi depth (m)	sd	x1	m
NOx	NOX.wm	Nitrite and Nitrate measured by microanalyser ($\mu\text{M/L}$)	NOx	x14	$\mu\text{g L}^{-1}$

3.3 AIMS FLNTU samples

Combination continuous Fluorometer and Turbidity Sensors (hereafter FLNTU) loggers were deployed at 15 of the AIMS MMP inshore water quality monitoring sites.

Table 5: Measures collected in AIMS MMP flntu inshore water quality monitoring program. Data used are daily means per site.

Measure	Variable	Description	Abbreviation	Conversion	Units
Chlorophyll-a	CHL_QA_AVG	??	chl	CHL_QA_AVG x1	$\mu\text{g L}^{-1}$
NTU	NTU_QA_AVG	??	ntu	NTU_QA_AVG x1	NTU

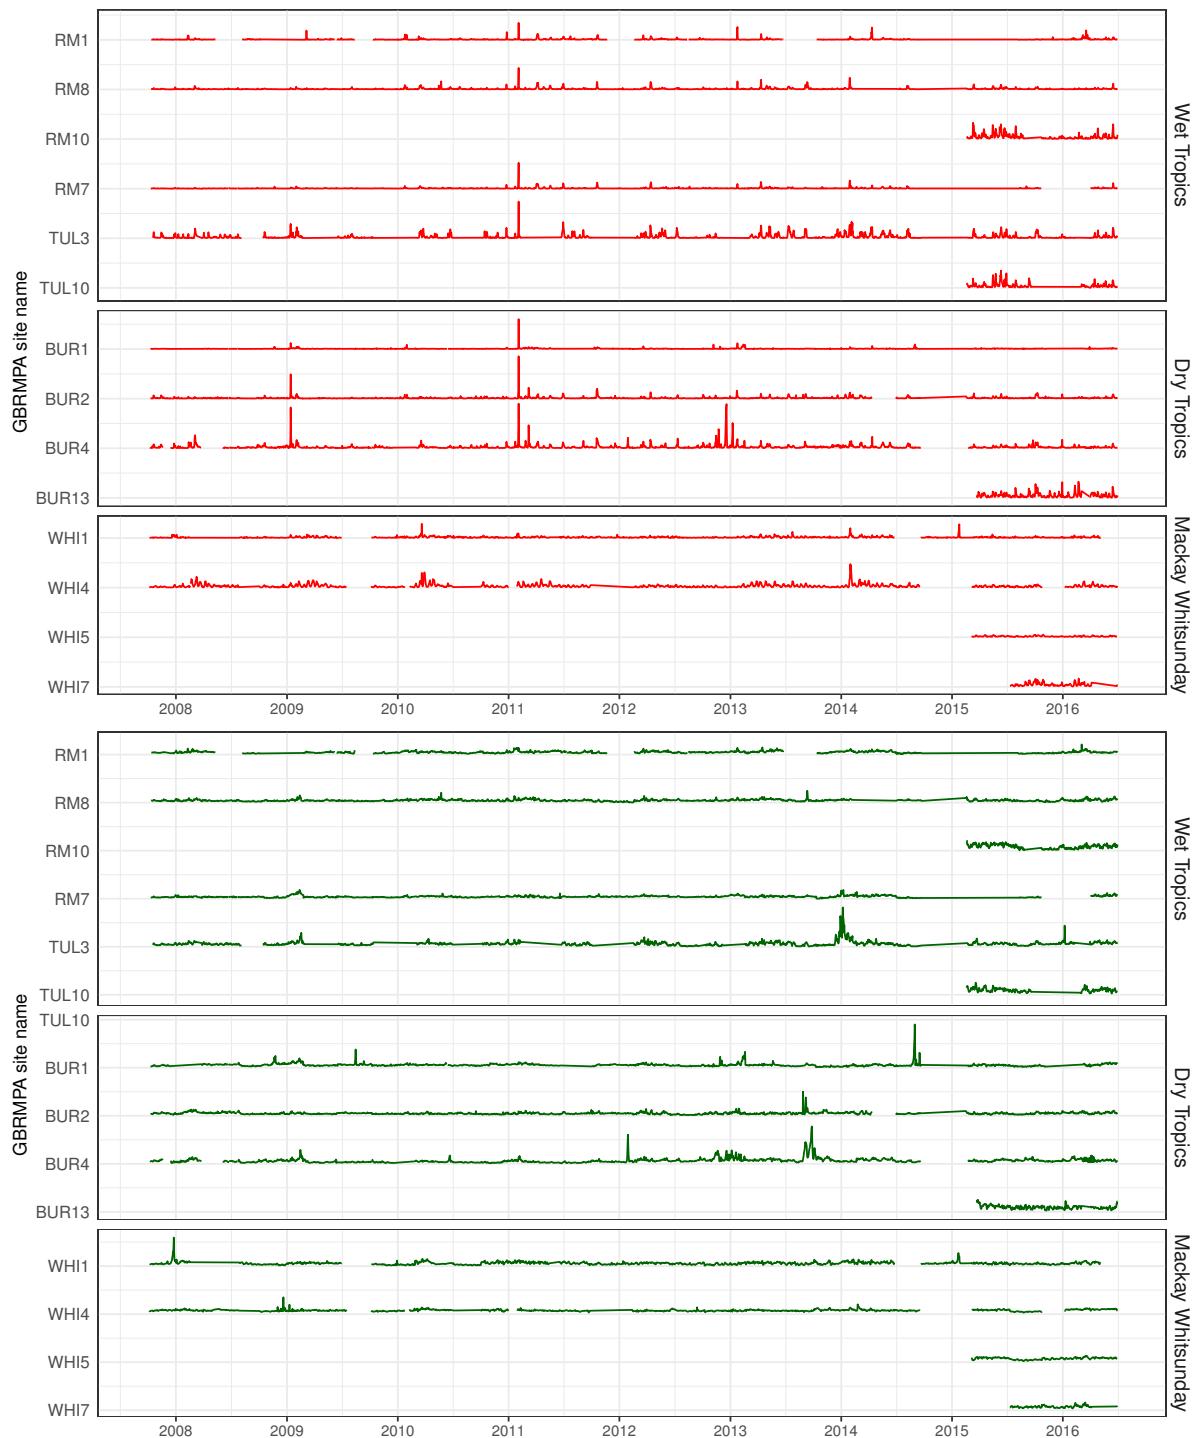

Figure 4: Spatial and temporal distribution of AIMS FLNTU samples (Red: NTU, Green: Chlorophyll-a). Sites names follow Great Barrier Reef Marine Park Authority (GBRMPA) and sites are arranged north to south into the focal Regions.

3.4 Remote sensing (BOM satellite)

Daily (July 2002–Dec 2016, $1 \times 1 \text{ km}^2$ resolution) Moderate Resolution Imaging Spectroradiometer (MODIS satellite) imagery (hereafter referred to as Satellite) data were obtained by downloading NETCDF files from the thredds server.

Table 6: Measures collected from MODIS satellite imaging. Data used are daily means per pixel. Variable and Description pertain to the eReefs source. Conversion indicates the conversion applied on data to conform to threshold Units. Abbreviation provides a consistent key across data.

Measure	Variable	Description	Abbreviation	Conversion	Units
Chlorophyll-a	Chl_MIM	??	chl	Chl_MIM x1	$\mu\text{g L}^{-1}$
Non-Algal Particles	Nap_MIM	??	nap	Nap_MIM x1	mg L^{-1}
Secchi Depth	SD_MIM	??	sd	SD_MIM x1	m

3.5 eReefs coupled hydrodynamic -- biogeochemical model

- We need a table that specifies and explains the naming of the various eReefs models and where they are available

The eReefs coupled hydrodynamic, sediment and BGC modelling system involves the application of a range of physical, chemical and biological process descriptions to quantify the rate of change of physical and biological variables (Fig. 5, Schiller et al. (2014)). The processes descriptions are generally based either on a fundamental understanding of the process (such as the effect of gravity on circulation) or measurements when the process is isolated (such as the maximum division rate of phytoplankton cells at 25°C in a laboratory mono-culture). The model also requires as inputs external forcings, such as observed river flows and pollutant loads. Thus, the model can be run without observations from the marine environment and in this mode is quite skilful (Skerratt et al. (submitted 9 Nov. 2017) and below). This mode which does not use observations from the marine environment as the simulation is undertaken is referred to as the non-assimilating simulation. Most of the eReefs marine biogeochemical simulations are non-assimilating.

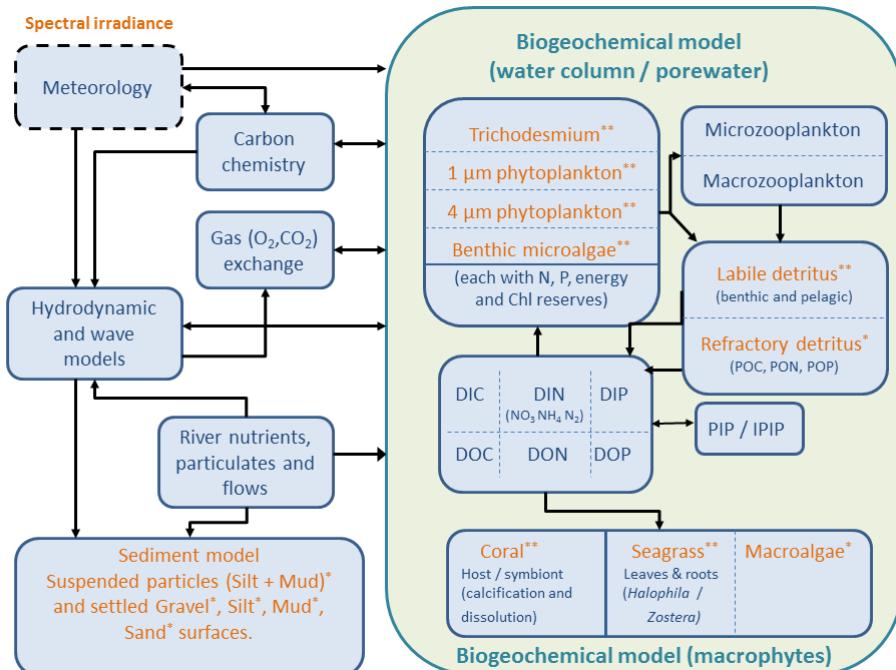

Figure 5: Schematic showing eReefs coupled hydrodynamic biogeochemical model.

Despite being already skilful, the predictive skill of the model can be improved by assimilating marine observations into an ensemble (i.e. a large number (108) of similar but not identical) of model simulations. The form of data

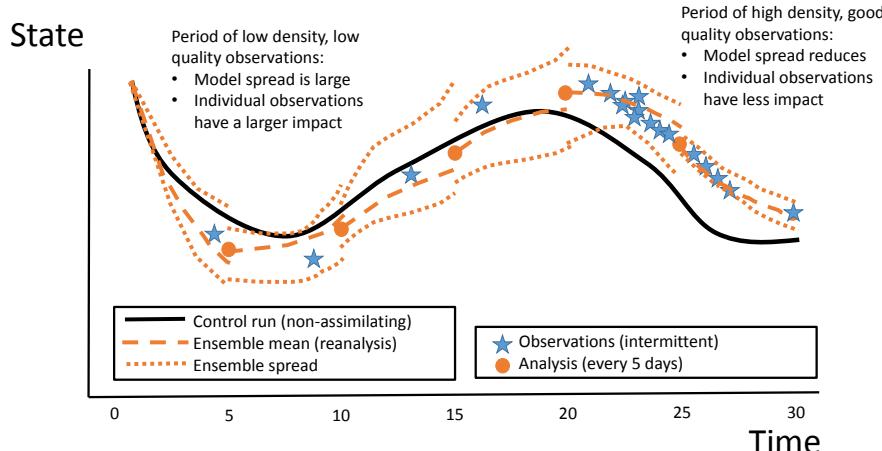

Figure 6: Schematic showing the evolution of the model ensemble over 6 assimilation cycles using the Ensemble Kalman Filter (EnKF) system. The non-assimilating control run (black line) is capturing the gross cycle in the observations (blue stars), but errors remain that observations can constrain. At the initial time, all ensemble members, and the control run, have similar values. In the first five days the 108 members develop a spread, with the control run being different to the ensemble mean, but within the ensemble spread. At 5 days, the first state updating occurs. In the first 5 days there was only one observations, being above the ensemble mean. At day 5, a new state for the entire ensemble is calculated (the analysis being the mean of the updated ensemble) based on the mismatch between the ensemble members and observations. The updated state is closer to the model if the ensemble spread is small, or to the observations if they are dense with few errors. At day 5, because of the small positive mismatch, the ensemble spread is only slightly narrowed, and the mean increased. The ensemble members all restart from these new updated states. The next four analysis steps proceed much like the first. For the fifth analysis step, high density observation were available over the previous 5 days, so the analysis is weighted heavily toward the observations, and the model spread is constrained significantly. Looking at the error between the ensemble mean and the observations over the entire period we see that the data assimilation system has provided an improved estimate of the state (the mean of the ensemble) relative to the control run, and achieved this using the model that contains the processes we understand to describe system.

assimilation we chose, and that is commonly used in weather forecasting, involves updating of the state of the model as the simulation progresses (Fig. 6). State updating involves first looking for a mismatch between the state of the ensemble members and the observations over the previous 5 days. Ocean colour, the observation of water-leaving irradiance at 8 individual wavebands, provides the only data set with sufficient temporal (daily) and spatial (1 km) resolution, providing upwards of 13 million pixels on a cloud-free day. For this comparison, we have chosen to use the mismatch between the model's prediction of the ratio of the water-leaving irradiance at 443 nm (blue) and 551 nm (green) and the observation of the same quantities from the MODIS sensor on NASA's Aqua satellite. The eReefs biogeochemical model is the first published model to assimilate raw ocean colour observations (Jones et al., 2016). The data assimilation algorithm uses the model-observation mismatch, as well as statistically-quantified dynamical properties of model, to periodically alter the values in the 108 member ensemble, resulting the ensemble mean gaining a closer match to the observations. The outcome of this modelling system is referred to in the field of data assimilation as a reanalysis.

Below we describe the model itself, and then particular data assimilation system.

3.5.1 eReefs coupled model description and forcing

The hydrodynamic model is a fully 3-D finite-difference baroclinic model based on the 3-D equations of momentum, continuity and conservation of heat and salt, employing the hydrostatic and Boussinesq assumptions (Herzfeld, 2006; Herzfeld et al., 2015). The sediment transport model adds a multilayer sediment bed to the hydrodynamic model grid and simulates sinking, deposition and resuspension of multiple size classes of suspended sediment (Margvelashvili, 2009; Margvelashvili et al., 2016). The complex BGC model simulates optical, nutrient, plankton, benthic organisms (seagrass, macroalgae and coral), detritus, chemical and sediment dynamics across

the whole GBR region, spanning estuarine systems to oligotrophic offshore reefs (Fig. 5, Baird et al. (2016)). An expanded description of the BGC model is given in Appendix A, with a brief description of the optical model in Appendix B. Briefly, the BGC model considers four groups of microalgae (small and large phytoplankton, Trichodesmium and microphytobenthos), two zooplankton groups, three macrophytes types (seagrass types corresponding to *Zostera* and *Halophila*, macroalgae) and coral communities.

Photosynthetic growth is determined by concentrations of dissolved nutrients (nitrogen and phosphorous) and photosynthetically active radiation. Microalgae contain two pigments (chlorophyll a and an accessory pigment) and have variable carbon : pigment ratios determined using a photoadaptation model (described in Baird et al. (2013). Overall, the model contains 23 optically active constituents (Baird et al. (2016); and Appendix A).

The model is forced with freshwater inputs at 21 rivers along the GBR and the Fly River in southwest Papua New Guinea. River flows are obtained from the DERM (Department of Environment and Resource Management) gauging network. Nutrient concentrations flowing in from the ocean boundaries were obtained from the CSIRO Atlas of Regional Seas (CARS) 2009 climatology (Ridgway et al., 2002).

The nutrient loads (TSS, PN, PP, DIN, DIP) for the 21 rivers were obtained from the process-based Source models used for Paddock 2 Reef (P2R) load reduction estimates (Waters et al., 2014). The P2R represent land uses and landscape processes in a variety of ways, often based upon spatially explicit farm-scale models that are included through a system of bespoke pre-processing and transfer tools. These P2R Source models also include flow related in-stream processing of pollutants, thus altering loads as fluxes transfer throughout the network. P2R modelling includes scenarios designed to represent 'baseline' (or 'current condition') and 'pre-development' catchment loads. In this report we only use 'baseline' condition. The reliance of the base P2R Source models on external, farm scale sub-models, means that they cannot be easily modified to extend the period covered by the report card. Thus we only use the P2R outputs from Jan 2011 - July 2014.

In order to provide daily timeseries predictions of pollutant loads past July 2014, the reliance on external sub-models was replaced by pollutant generation models that estimate daily loads through monthly varying concentrations ('EMC/DWC'). The particular concentration values for each pollutant for each Functional Unit (FU) within each subcatchment have been calculated by analysing the monthly runoff volumes and pollutant loads from the P2R Source models defined in Waters et al. (2014). The network transport and in-stream processing mechanisms are unaltered from the base P2R Source models. These monthly concentration pollutant generation models allow the model predictions to be extended by providing updated rainfall runoff model inputs (i.e. the runoff of the day), without the need to also update many thousands of farm scale sub-models. Simple comparisons of predicted loads indicates that the monthly varying concentration approach works reasonably well for sediment and associated particulate nutrient, and less well for pollutants that are usually reliant on farm scale representation of management inputs.

3.5.2 Assimilation system

3.5.2.1 Assimilation of ocean colour

Ocean colour was chosen as the data set to assimilate due to its availability over the entire GBR at high temporal and spatial density. Ocean colour has often been used for biogeochemical data assimilation (Kidston et al., 2013). In global biogeochemical data assimilation applications, the observation - model mismatch used has often been satellite estimates of *in situ* chlorophyll concentration versus model predicted chlorophyll concentration (Ford et al., 2012). This approach is problematic in coastal waters such as the GBR, where chlorophyll concentration is often overestimated by satellite algorithms due to bottom reflectance or absorption by non-phytoplankton components (Schroeder et al., 2012). So it is not possible in this application to base the data assimilation system on the mismatch of model chlorophyll against satellite estimates of *in situ* chlorophyll. Instead, we have pioneered the use of remote-sensing reflectance as the variable to determine the mismatch between the observed and modelled quantities (Jones et al., 2016).

Remote-sensing reflectance, R_{rs} , is the ratio of the water-leaving irradiance in the direction of a satellite to the water entering radiance. In this sense it is a 'raw' satellite observation. The value of R_{rs} varies with wavelength and is measured in sr^{-1} (sr = steradians, the SI unit of solid angle, where the solid angle in all directions on a spherical surface is $4\pi \text{ sr}$). In the open ocean at blue wavelengths the value is around 0.03 sr^{-1} (Baird et al., 2016). That is, 3 % of the light that entered the ocean within 1 m^2 emerged travelling in the direction within a solid angle of 1 sr (i.e. $1/4\pi$ of a sphere).

The model contains 23 optically active constituents (shaded orange in Fig. 5, see also Baird et al. (2016)). For each of these constituents the optical model calculates the rate of absorption, scattering and backscattering. To

calculate R_{rs} at the surface, we need to consider the light returning from multiple depths, and from the bottom. Rather than using a computationally expensive radiative transfer model, we approximate R_{rs} based on an optical-depth weighted scheme (Baird et al., 2016). The model sums the return from each depth (and the bottom) to give the surface R_{rs} . As shown in Baird et al. (2016), this calculation is sufficiently accurate that the primary reason for the mismatch between observed and modelled R_{rs} is errors in the coupled hydrodynamic-biogeochemical model prediction of optically-active constituents. This is, of course, the result we wanted - it means that when the assimilation system updates the optically-active biogeochemical constituents in order to minimise the mismatch between observed and modelled R_{rs} , it is changing the components of the model that have the greatest errors, and in doing so improving the solution of those parts that we most care about - the optically-active components that determine water clarity.

When testing the data assimilation system, we found that the best quantity to assimilate was the ratio of the remote-sensing reflectance at 443 and 551 nm. In fact, this ratio is the same one used in the NASA OC3M algorithm that we mentioned above is NOT a good measure of *in situ* chlorophyll in coastal waters! So how can it be that OC3M is a poor predictor of *in situ* chlorophyll in coastal waters, yet assimilating the mismatch between simulated OC3M and satellite-observed OC3M achieves the best skill for *in situ* chlorophyll when compared against independent *in situ* observations? The answer lies in that simulated OC3M is calculated using the ratio of two simulated R_{rs} , in the same manner in which observed OC3M is calculated using the ratio of two observed R_{rs} . Fig. 7 shows the *in situ* chlorophyll concentration, the simulated OC3M and the NASA observed OC3M for the Cape York region on a relatively clear day. The *in situ* chlorophyll concentration in coastal regions along this coast is $\sim 0.5 \text{ mg m}^{-3}$ (Fig. 7 left). The simulated OC3M, calculated from simulated R_{rs} , is greater along the coastal fringe due to the absorption of blue light from CDOM, and addition bottom reflection of green light (Fig. 7 centre). The observed OC3M, also affected by CDOM absorption and the bottom, looks more like the simulated OC3M than the *in situ* chlorophyll concentration (Fig. 7 right). Further, where there are differences, the primary cause is the error in the simulated water-column optically-active constituents like chlorophyll. Thus by producing the same simulated and observed quantity, we have improved the ability of the assimilation system to update the optically-active model constituent that is in error.

OC3M uses the ratio of above-surface remote-sensing reflectance as a combination of three wavelengths, R' , which is given by:

$$R' = \log_{10} (\max [R_{rs,443}, R_{rs,488}] / R_{rs,551}) \quad (1)$$

The ratio R' is used in the OC3M algorithm to estimate surface chlorophyll, Chl_{OC3} , with coefficients from the 18 March 2010 reprocessing:

$$\text{Chl}_{OC3} = 10^{0.283 + R'(-2.753 + R'(1.457 + R'(0.659 - 1.403R')))} \quad (2)$$

obtained from oceancolor.gsfc.nasa.gov/REPROCESSING/R2009/ocv6/. Using OC3M we gain the benefit of assimilating directly the mismatch between the simulated OC3M (based on simulated remote-sensing reflectance) and the observed remote-sensing reflectance; and we use a quantity that has meaning in the water quality community (mass concentration of chlorophyll). To re-state, because we use the simulated remote-sensing reflectance to calculate OC3M, the system is not affected by the inaccuracies in the relationship between *in situ* chlorophyll and satellite-derived OC3M. And our assimilation system's prediction of chlorophyll is the simulated *in situ* chlorophyll concentration (and not OC3M).

The accuracy of the modelling systems also requires that the model and observations are closely matched in space and time. This is because remote-sensing reflectance is a function of solar angle (and therefore time of day), and because the optical properties of coastal waters can vary quickly due to a range of processes such as phytoplankton chlorophyll synthesis, movement of fronts, wind driven-upwelling, river plume structure changes etc. We used the flexible outputting time of the model, and the asynchronous assimilation routines in the EnKF-C package (Sakov, 2017), to closely align the observations and models. In doing so we were able to meet the ± 30 minutes matching requirements used for the calibration / validation of ocean colour satellite products.

The Aqua satellite overpasses the GBR between 1130 and 1530 locally. In order to match the model output to within 30 minutes of the overpass, the model remote-sensing reflectance was output at 1200, 1300, 1400 and 1500 daily. For the calculations of remote-sensing reflectance, the water column calculations of the light field (and R_{rs}) was redone on the output time assuming the entire grid is at 150°E , while in fact it varies from $142^\circ 31'\text{E}$ to $156^\circ 51'\text{E}$. Thus the maximum error in calculating solar angle for the purposes of outputting R_{rs} , in the Torres Strait, is about 30 minutes (this small error will be corrected in the next phase of eReefs). The light field calculation was also done at wavelengths at the centre of the MODIS ocean colour bands to avoid any small interpolations from the spectrally-resolved model that has a 20 nm resolution.

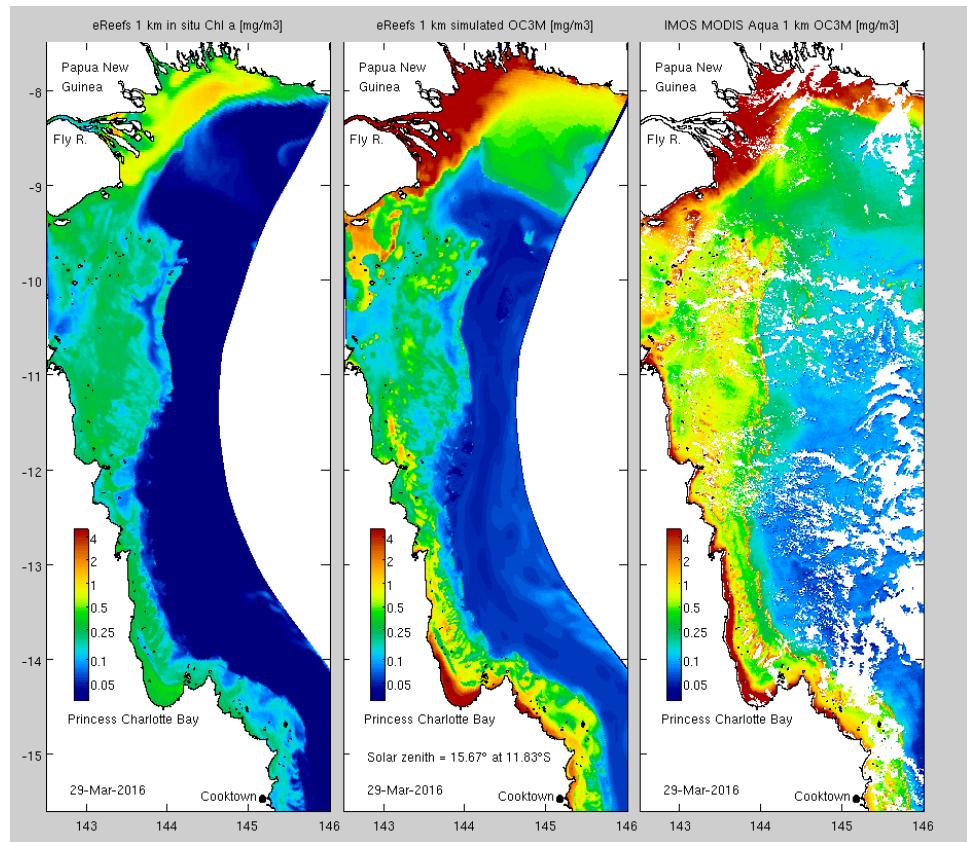

Figure 7: Example of the estimates of OC3M in the Cape York region on the 29 March 2016 using the 1 km GBR1 model and the NASA Aqua MODIS sensor: *in situ* chlorophyll concentration (left), the simulated OC3M (centre) and the NASA observed OC3M (right).

The observations also need to be spatially aligned. The observations are at approximately ~ 1 km resolution (up to 2 km on the edges of the swath), with location varying spatially with each different satellite swath. Meanwhile the model cells are stationary, are $\sim 16 \text{ km}^2$, and are defined on the curvilinear grid. The observations are grouped into a "superobservation" for each model cell. The superobservation contains all observations that were closer to a particular cell centre than any other cell centre. The position of the superobservation is the mean of the observations it is composed of, and will be close to, but not exactly the same, as the location of the cell centre. The assimilation system then accounts for the now small misalignment in time and space when considering the mismatch between the model and observation.

3.5.2.2 Ensemble member design

The assimilation system used in this study is the Deterministic Ensemble Kalman Filter (DEnKF) that requires an ensemble of model runs that approximate the uncertainty in the model solution. The uncertainty in the model solution arises from uncertainty in the model initial conditions, boundary conditions, surface forcing and model parameterisations. The ensemble members differ in the values of the quadratic mortality rate coefficient of small zooplankton, in the loads of nutrients delivered in the rivers (as a multiple of the SOURCE catchments specified loads), and in the PAR light forcing (again as a multiple of the Bureau of Meteorology short wave radiation prediction). These relatively small differences, which are undertaken on the most uncertain biological parameter, and most sensitive forcing parameters, provide a spread of ensemble members that the Kalman Filter can operate on.

For a further description of the numerical schemes in the assimilation system see (Jones et al., 2016). A number of modifications have been made to improve the accuracy and efficiency of the system, including transferring the EnKF-C software.

3.5.3 Summary results

The non-assimilating version of the model has been compared to observations previously (ereefs.info, Baird et al. (2016) and Skerratt et al. (submitted 9 Nov. 2017)). The results produced in the reanalysis are compared directly to observations in the attached 100 page appendix showing comparisons to hundreds of time-series. Further, later components of this document compare the metric calculated using the non-assimilating model, the assimilating model, satellite observations and *in situ* observations. Here we will just show a few snapshot results to aid in the understanding of the performance of the data assimilation relative to the non-assimilating run.

3.5.3.1 Assessment of chlorophyll concentration at MMP sites

In our assessment of the skill of the eReefs biogeochemical models, we have considered the most important property to be the prediction of *in situ* chlorophyll concentration at the MMP sites. For this there are two measures - the chlorophyll extractions at the sampling sites, and the calibrated chlorophyll fluorescence on the moorings. While the extractions are considered the most accurate, the fluorescence time-series is continuous. When the two are lined up in time (they are slightly separated in space), the mismatch between the observed chlorophyll extractions and the observed chlorophyll fluorescence is 0.2 mg m^{-3} . We use this 0.2 mg m^{-3} as indicative of the error of the observations.

It is important to note that the *in situ* chlorophyll concentration observations were not assimilated into the model. That is, they were observation withheld just for the model assessment. In fact, the mismatch between observed and modelled quantities used in the assimilation system is neither an *in situ* measurement, nor a chlorophyll concentration. The assimilated quantity was the ratio of remote-sensing reflectance at blue and green wavelengths. Thus, we can be confident that if the assimilation system has improved the prediction of *in situ* chlorophyll concentration then it has improved the overall biogeochemical model.

At 13 of the 14 MMP site, the assimilation of satellite-observed remote-sensing reflectance improved the prediction *in situ* chlorophyll concentration (Fig. 8, top). On average the assimilation reduced the error from 0.34 mg m^{-3} to 0.29 mg m^{-3} , bring it 30 % closer to the observation error (the limit of our ability to quantify an improvement in the model). The worst two site remained the most coastal sites, Geoffrey Bay and Dunk Island, for which the 4 km model poorly resolves local processes, and for which the assimilation system would provide little information to water column due to the optically-shallow and complex waters. The best site was Double Cone Island off Airlie Beach. At Double Cone Island, a time-series shows the improvement in the chlorophyll fluorescence due to the assimilation (Fig. 8, bottom). During a particularly cloud-free period in the second half of 2015, the assimilation system does a remarkable job of both removing model bias and capturing variability in the model.

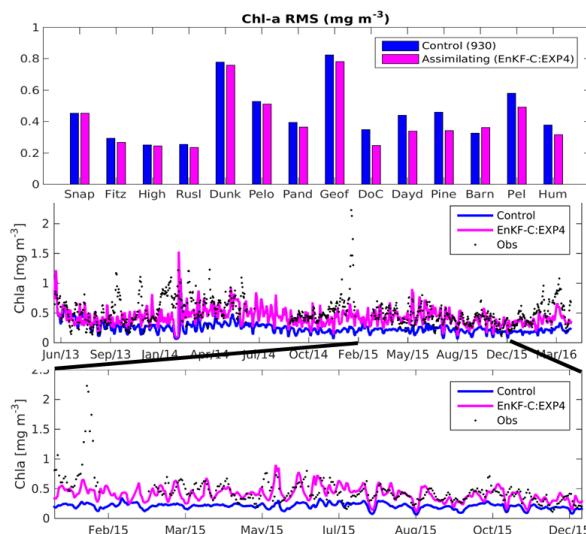

Figure 8: Comparison of the non-assimilating (blue) and assimilating (pink) runs at the MMP sites. The instantaneous state root mean square error at the 14 MMP sites (top). The approximate error in the observations is 0.2 mg m^{-3} . At Double Cone Island in the Whitsundays (off Airlie Beach), a time-series of the observations (black dots) and simulations is shown for the whole simulations (centre) and the a 1 year period (bottom).

In this context, the **eReefs** model refers to the gbr4_bgc_?? model (see Table?? for the catalog and model descriptions and Table7 for a description of the variables and processing).

This source of data only extends back to 2014. Whilst the eReefs GBR4_BGC_? model technically does contain 2013 calendar year data, the current project partitions time into water years in which the full 2013 water year starts in October 2012. Therefore as the 2013 is not a complete 12 months of data, it is excluded from analyses. Unfortunately, this means that any signals associated with the 2010-2011 floods are unavailable.

Table 7: Measures collected from eReefs assimilated model. Data used are daily means per pixel. Variable and Description pertain to the eReefs source. Conversion indicates the conversion applied on data to conform to threshold Units. Abbreviation provides a consistent key across data.

Measure	Variable	Description	Abbreviation	Conversion	Units
Chlorophyll-a	Chl_a_um	Sum of Chlorophyll concentration of four microalgae types (mg/m^3)	chl	Chl_a_um x1	μgL^{-1}
Non-Algal Particles	EFI	??	nap	EFI x1000	mgl^{-1}
Secchi Depth	Kd_490	??	sd	I/Kd_490	m
NOx	NO3	Concentration of Nitrate. As Nitrite is not represented in the model, NO3 = $[NO_3^-] + [NO_2^-]$ (mg/m^3)	NOx	NO3 x1	μgL^{-1}

3.6 eReefs926

In this context, the **eReefs926** model refers to the gbr4_bgc_926 model (see Table??). This model provides alternative formulation and importantly does extend back to the full 2013 water year thereby providing some coverage closer to the 2010-2011 flood period.

Variables used as per Table 7

3.7 Thresholds

An environmental health metric represents the state or condition relative to some reference, threshold or expectation. Most of the current water quality indices compare values to a set of specifically selected guidelines. These guidelines are either formulated specifically from long-term historical data appropriate to the spatial and temporal domain of interest or else are based on ANZEC guidelines (Australian and New Zealand Environment and Conservation Council, 2000).

Typically there are strict guidelines on how these guidelines should be applied. In particular, the guidelines associated with various measures used in various report cards throughout the Great Barrier Reef should be applied to annually aggregated data - not individual observations. Since this project intends to generate indices on the scale of individual observations, we have decided to refer to the guidelines as *thresholds* so as to avoid contradicting the terms of use of guidelines..

The thresholds used for each Measure within each Region and Water body are indicated in Table A1 (page 177). Note, that whilst the application of seasonal thresholds could potentially remove some uncertainty, in the absence of clear consensus on how to define wet and dry seasons and what the associated set of thresholds would be, seasonal thresholds are not used in this project.

4. EXPLORATORY DATA ANALYSIS

Exploratory data analysis is vital for informing data processing and analysis as well as establishing assumptions and limitations. Of particular importance for the current project is the spatial and temporal distribution and variability of the various data Measures and Sources. As such, a series of exploratory plots have been generated (see Appendix C.1 beginning on page 183). In the interest of keeping the main text free of copious graphics, we have elected to present only a small fraction of the exploratory data analyses figures here. The figures presented will act as exemplars of general format and predominant features or patterns.

4.1 All data

Figures 9 – 12 display the temporal distribution of Chlorophyll-a, TSS, Secchi depth and NOx observations for the Wet Tropics Open Coastal Zone from AIMS insitu, AIMS FLNTU, Satellite, eReefs and eReefs926 sources.

All of the figures are presented with log-transformed y-axes as the data are typically positively skewed. This is expected for parameters that have a natural minimum (zero), yet no theoretical maximum. It does however mean that these distributional properties should be considered during the analyses. In particular, for mean based aggregations, outliers and skewed distributions can impart unrepresentative influence on outcomes.

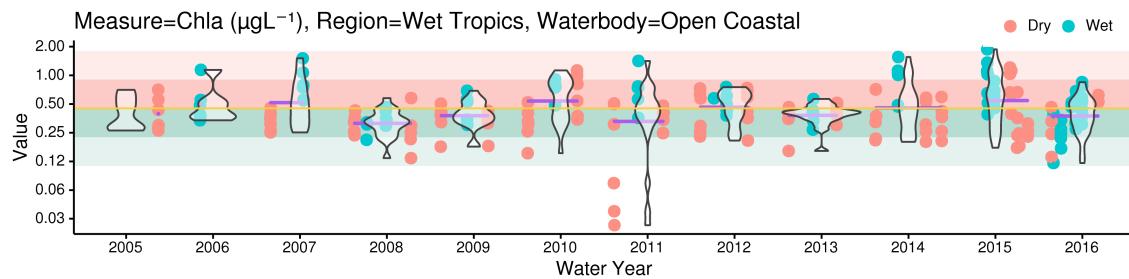

Each of the data sources present different variability characteristics. The scale of the range of AIMS insitu data is predominantly and approximately less than or equal to the scale of the half/twice the associated threshold value (Fig. 9-12a). The AIMS FLNTU logger data (Fig. 9-12b) have a larger range than the AIMS insitu data - presumably because the former data collection frequency captures most of the peaks and troughs whereas the later are unlikely to do so. Furthermore, whilst the AIMS insitu data are predominantly collected during the dry season, the AIMS FLNTU loggers collect data across the entire year and are therefore likely to record a greater proportion of the full variation in conditions. Of course it is important when interpreting these diagnostic plots to focus mainly on the violin plots and less on the dots (representing individual observations). This is because the dots do not provide an indication of the density and it is easy to allow outliers to distort our impression of the variability of the data.

Similarly, the scale of the range eReefs and eReefs926 data (Fig. 9-12d-e) is approximately equal to the scale of the range of the span from half/twice the threshold value. This reflects both a more complete time series and broader spatial extent represented in the data. In contrast to the AIMS insitu and to a lesser extent the AIMS FLNTU and eReefs data, the scale of the range of the Satellite is relatively large - typically a greater span than the range of half/twice threshold value (Fig. 9-12c).

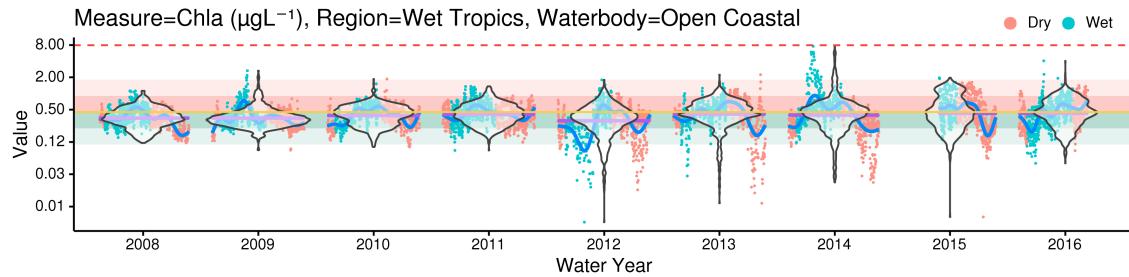

The Satellite, eReefs and eReefs926 data series all start and end part of the way through a water year. For annually aggregated data, this is likely to result in unrepresentative estimates and thus only full water years will be analysed.

4.2 Annual data

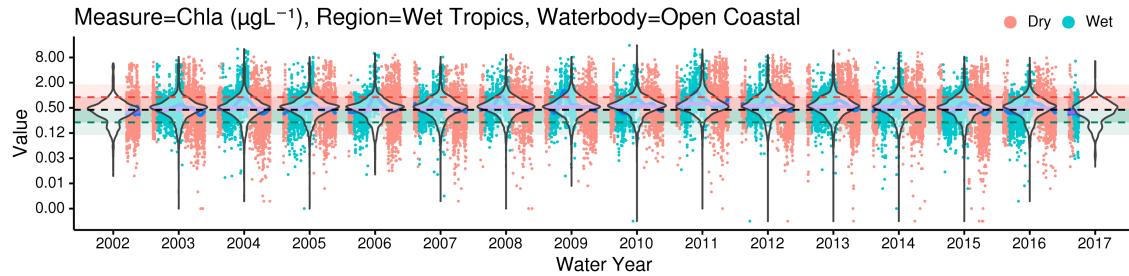

a) AIMS insitu

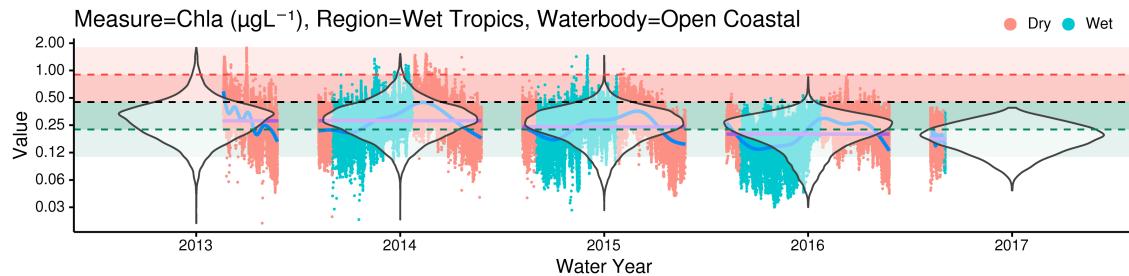

b) AIMS FLNTU

c) Satellite

d) eReefs

e) eReefs926

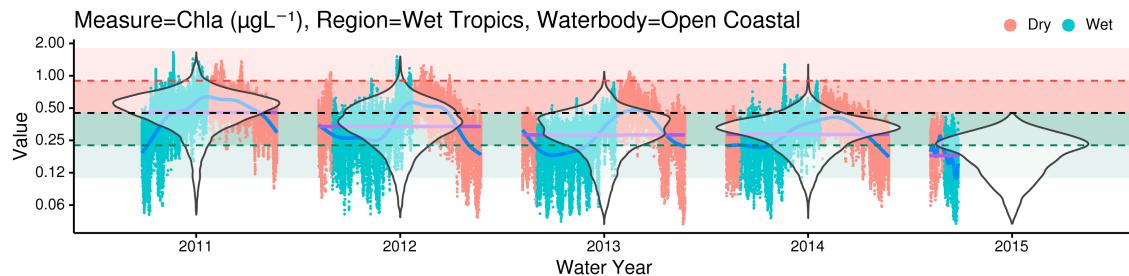

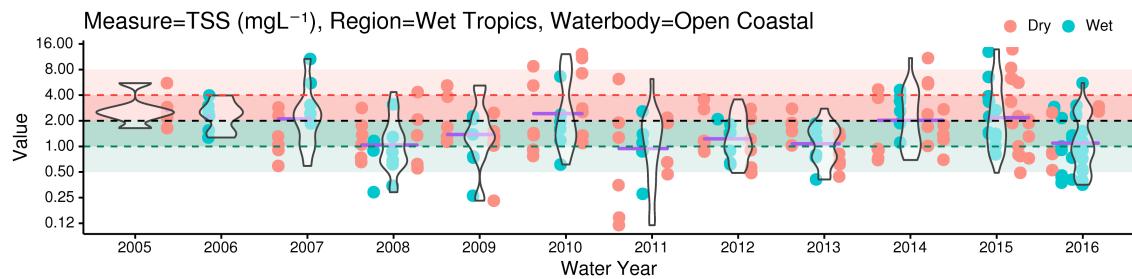

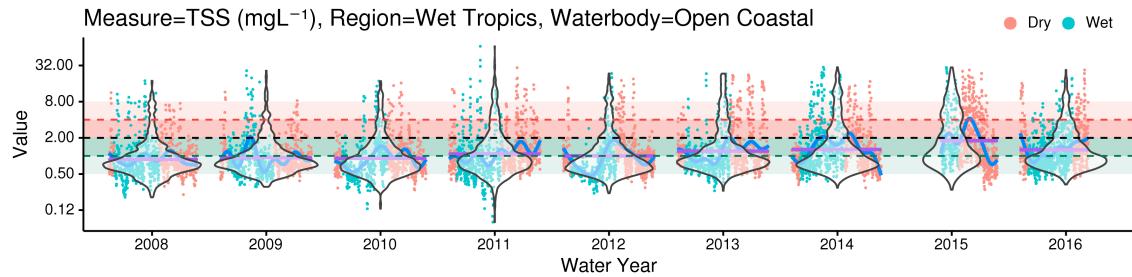

Figure 9: Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

c) Satellite

d) eReefs

e) eReefs926

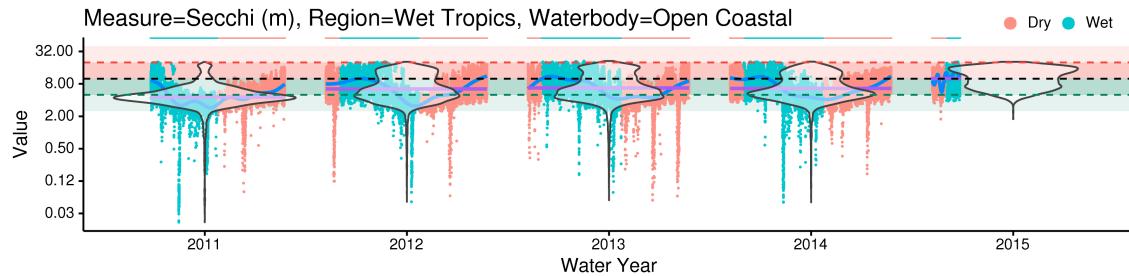

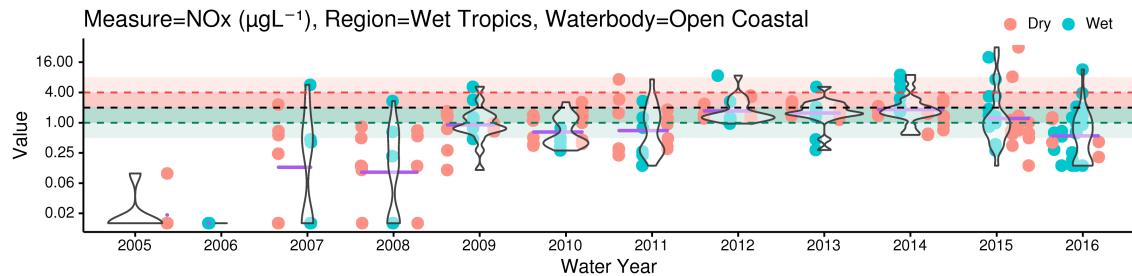

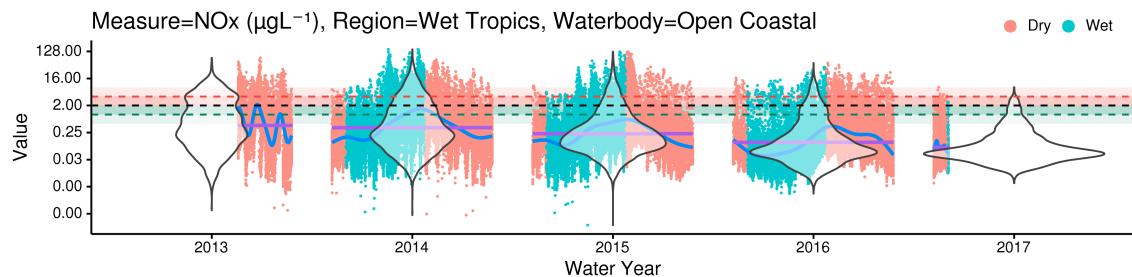

Figure 11: Observed (logarithmic axis with violin plot overlay) Secchi depth data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $\times 4/4$; 30% shade: $\times 2/2$) above and below threshold respectively.

a) AIMS insitu

b) eReefs

c) eReefs926

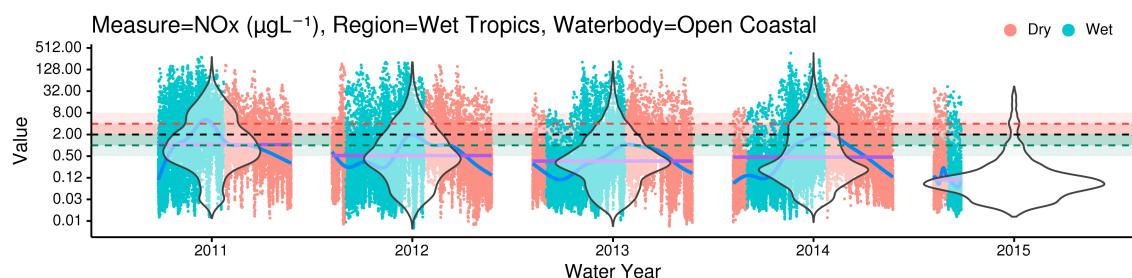

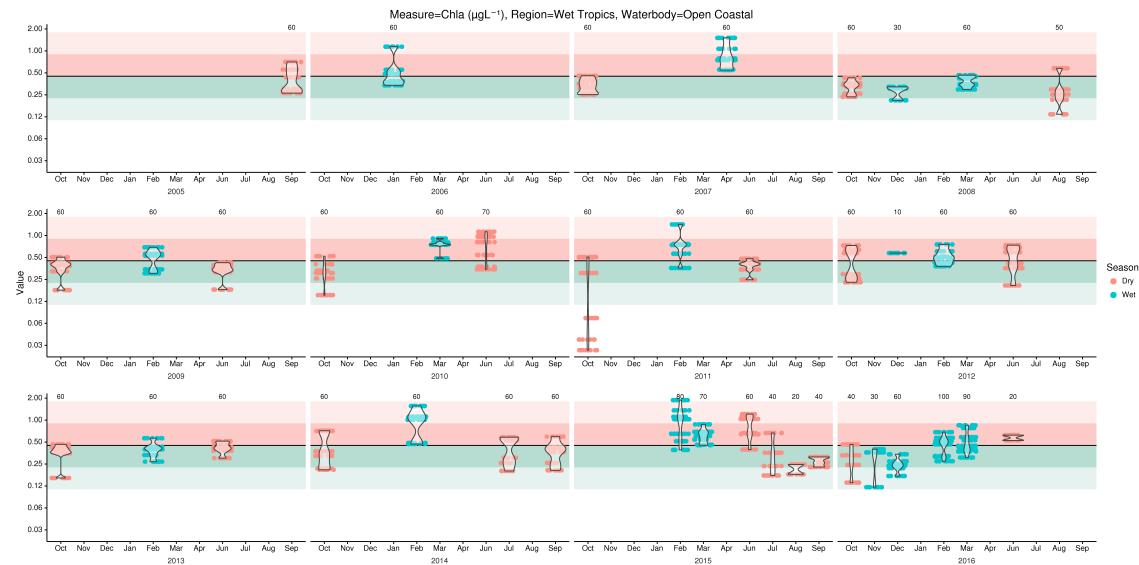

Figure 12: Observed (logarithmic axis with violin plot overlay) NOx data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) eReefs and c) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

4.3 Monthly data

Figures 13 – 18 provide finer temporal resolution by displaying the temporal distribution of Chlorophyll-a, TSS, Secchi depth and NOx observations for each month within Wet Tropics Open Coastal Zone from AIMS insitu, AIMS FLNTU, Satellite, eReefs and eReefs926 sources.

The monthly violin plots do not add any additional insights with respect to understanding the characteristics of the underlying data to help guide the selection of appropriate indexation formulation or perhaps even Measure/Source selection. Rather, they provide a less compacted view of the underlying data from which patterns highlighted in Section 4.2 might be more easily appreciated.

a) AIMS insitu

b) AIMS FLNTU

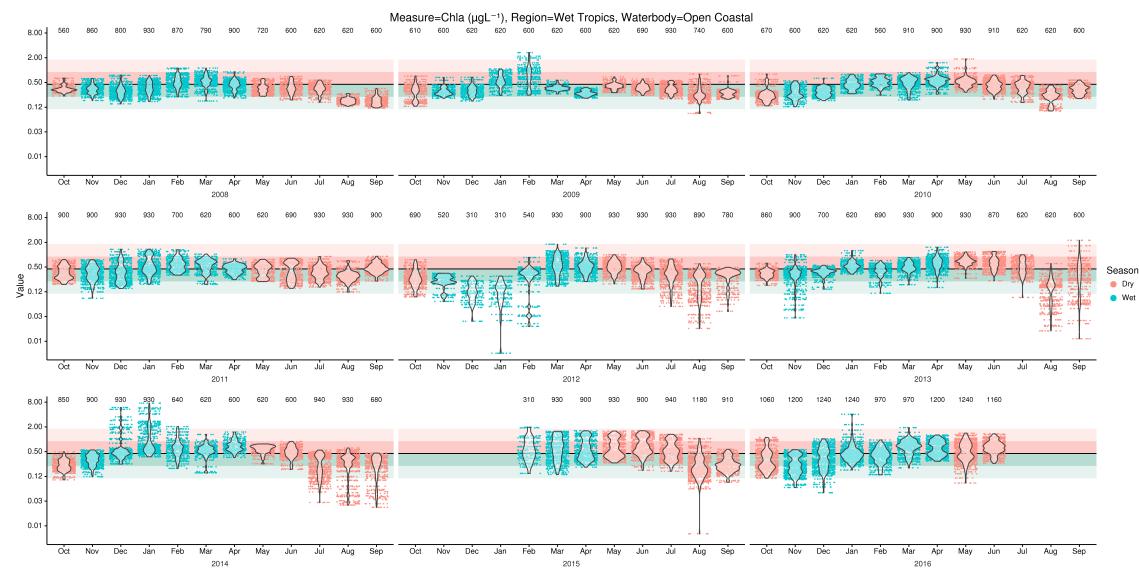

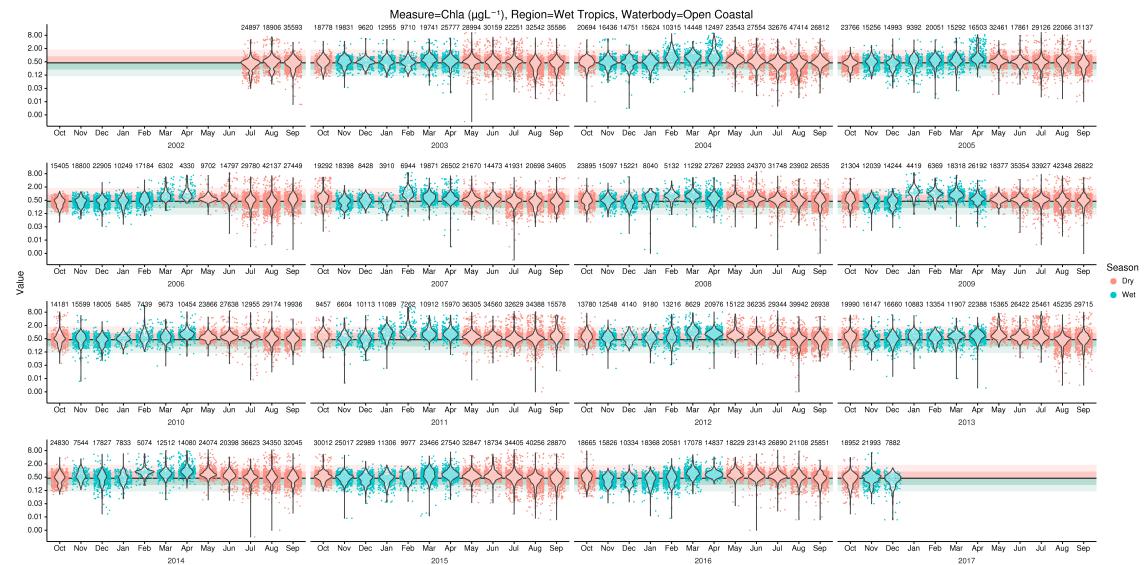

Figure 13: Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Wet Tropics Open Coastal Zone from a) AIMS insitu, b) AIMS FLNTU. Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

Observations grouped into months are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Sample sizes represented as numbers above violins and horizontal black dashed line denotes threshold value. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

4.4 Spatial data

Figures 19 – 26 explore the spatio-temporal patterns in observed data from a finer spatial perspective (again focussing on just the Wet Tropics Open Coastal and Dry Tropics Midshelf Zones). Importantly, the colour scales have been mapped to a constant value range for each source for a given Measure. The lower and upper bounds of the constant range is respectively based on twice and half the threshold (see Table A1) value (except for Secchi depth which are half and twice respectively). Half and double the threshold was considered broadly appropriate for the Insitu data and thus should also be broadly appropriate for the other sources since they are intended to be indirect approximations of direct sampling.

These figures also highlight the disparity in resolution between the different data sources. The AIMS insitu data is spatially very sparse¹. The Satellite data has the most extensive spatial resolution and notwithstanding the many gaps due to various optical interferences (such as cloud cover), also has the greatest temporal coverage².

For the selected Zones and span of water years, there is little evidence of a major latitudinal gradient in Satellite Chlorophyll-a with most of any change (if any) occurring across the shelf. Indeed, Satellite parameters are relatively constant over space and time for the Dry Tropics Midshelf Zone (see Figs. 23–25b). Moreover, the spatial patterns of Satellite derived Chlorophyll-a and TSS appear relatively invariant between years (see Figs. 19–25b).

The eReefs and eReefs926 do show some variability in spatial and temporal Chlorophyll-a and Secchi depth (see Figs. 19c-d, 21c-d, 23c-d and 25c-d), yet relatively little for TSS and NOx (at least for Dry Tropics Midshelf). Whilst this apparent lack of variability is largely an artefact of the colour scale mapping, the values of these Measures are constantly substantially below the threshold value and thus invariant on the scale considered appropriate for comparison against the associated thresholds..

¹the AIMS FLNTU logger data is even more sparse and thus is not shown.

²The remote sensing Satellite data span a temporal range of 2002 through to 2017, although only the range 2010-2016 is displayed

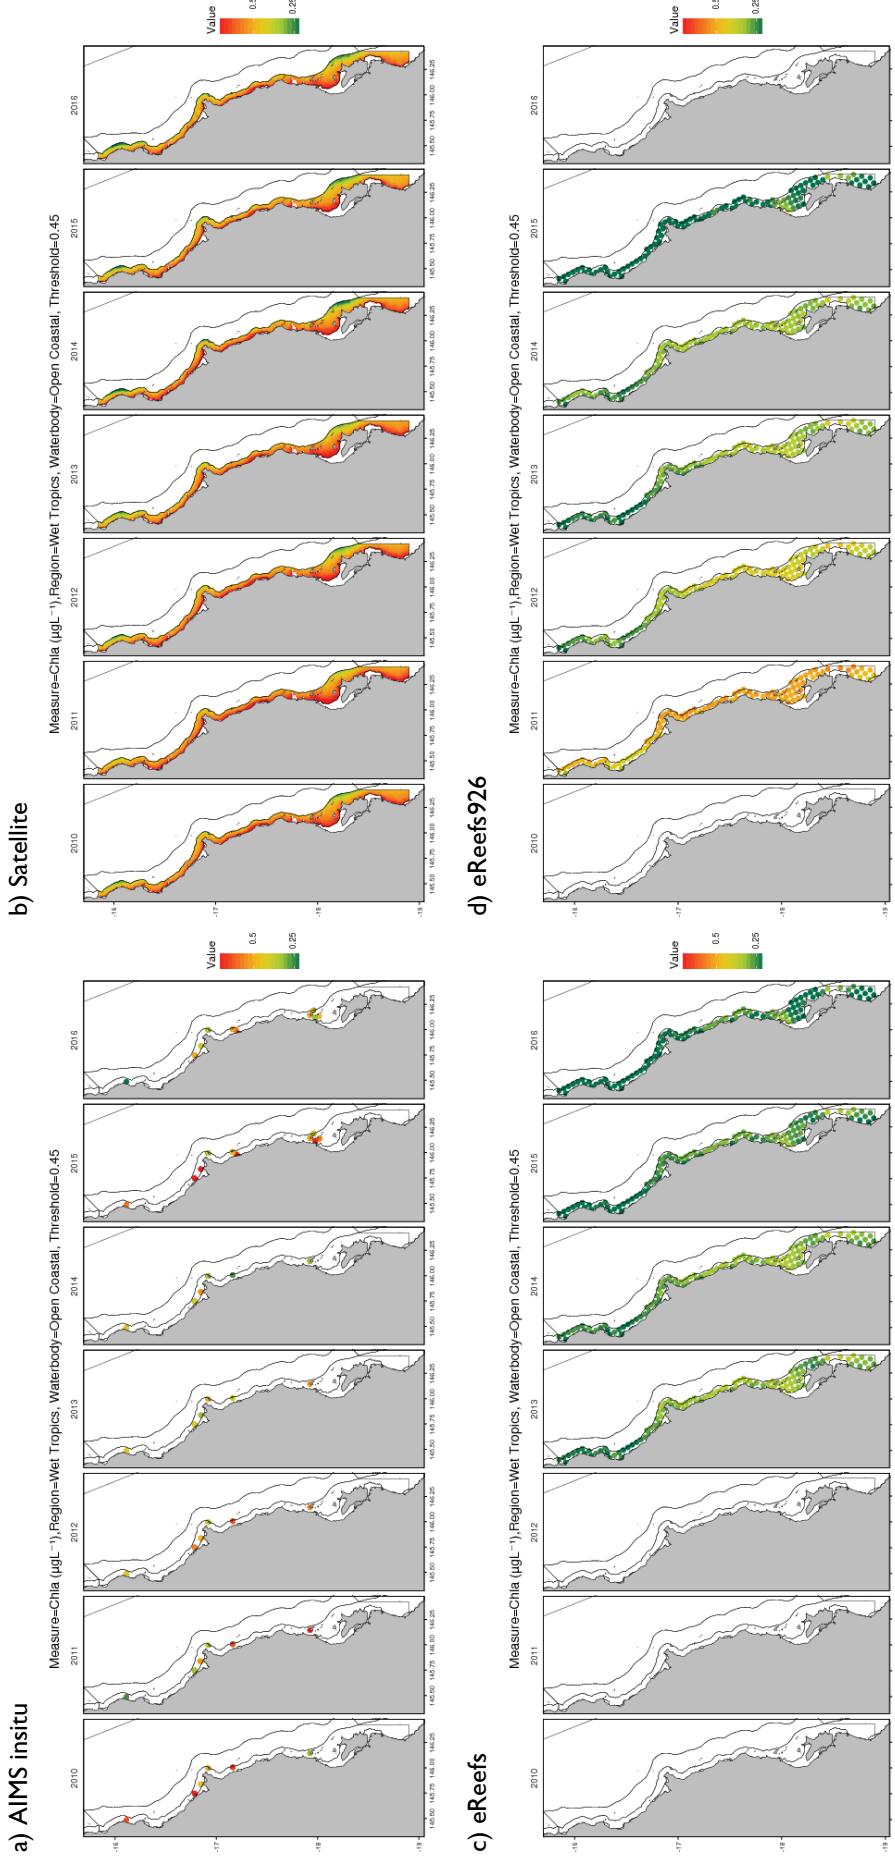

Figure 19: Spatial distribution of observed a) AIMS insitu, b) Satellite, c) eReefs and d) eReefs926 Chlorophyll-a (2009–2016) for the Wet Tropics Open Coastal Zone.

4.5 Comparison of data sources

Ensuring that the data underpinning the metric calculations are fit-for-purpose is a critical part of the process, especially if multiple data sources for a specific indicator are to be aggregated as part of these calculations. For example, successful aggregation of Chlorophyll-a as modelled by the eReefs BGC with Chlorophyll-a as extracted from satellite reflectance data (optical properties) will largely depend on the underlying compatibility of these two sources. Moreover, further combining with far more sparse and irregular sources (such as AIMS insitu Chlorophyll-a samples) relies on general patterns of spatial and temporal autocorrelation being present across the more dense data sources so as to facilitate a contagious projection of sparse data across the denser layers.

Based on substantial inconsistencies in the magnitude and variation of the observations between sources (AIMS insitu, Satellite and eReefs models), we recommend not to aggregating across the streams of data. Although it might be possible to normalize each source such that they do all have the same basic characteristics prior to aggregation³, all the various approach to achieve normalization rely on the availability of independent estimates of either data reliability, accuracy or biases present in each source. Unfortunately, such information is not available.

Instead of aggregating the sources together, the preferred approach is to assimilate satellite reflectance information into the eReefs BGC model and to rely on in situ measurements for verification of the model performance.

It is worthwhile noting that there is no single point of truth as the sparse insitu sampling does not account for the dynamic nature of the receiving environment, both temporally and spatially. It is however possible to compare different measurement methods at a high level.

The five different sources (Satellite, eReefs, eReefs926, AIMS Insitu and AIMS FLNTU loggers) were all collected at different spatio-temporal resolutions. Specifically:

- the Satellite data are collected on a 1km grid on a daily basis, however there are many gaps in the time series of each cell due to cloud cover and other issues that affect the reliability of observations.
- the eReefs data are modelled and projected on to a 4km grid on a daily basis without any time series gaps between 2013 and 2016
- the eReefs926 data are modelled and projected on to a 4km grid on a daily basis without any time series gaps between 2011 and 2014
- the AIMS Insitu samples are collected from specific sampling sites (28-32 throughout the GBR) and on an infrequent basis (approx. 3-4 times per year although more frequently in later years). Furthermore, with the exception of relatively recently, the majority of samples were collected in the dry season and thus these samples could be biased towards long term water quality trends rather than short-term pulses.
- the AIMS FLNTU logger data are deployed at a subset (16) of the AIMS Insitu sampling locations and record measurements every 10 minutes (although there are frequent gaps due to instrument failure).

The AIMS Insitu sampling locations are strategically positioned so as to generally represent transects away from major rivers discharging into the GBR. As such, they likely represent biased estimates of the water parameters of the surrounding water bodies. Nevertheless, the observed data are direct measurements of a range of parameters considered to be important measures of water quality and are therefore considered to be relatively accurate estimates of the true state - albeit for a potentially narrow (and biased) spatio-temporal window. By contrast, the Satellite data represent indirect proxies for some of these parameters (Chlorophyll-a, Total Suspended Solids and Secchi Depth) and similarly, the eReefs data are indirect modelled estimates simulated from a deterministic manifestation of a conceptual model. Hence, to gauge the accuracy of the Satellite and eReefs data (and thus inform qualitative confidence), time series and spatial patterns in the Satellite and eReefs observations were compared to the AIMS Insitu observations.

The disparate spatio-temporal resolutions of the data sources present substantial challenges for extracting comparable data. For example, the proximity of AIMS Insitu samples to reefs and the spatial resolution (1km or 4km grid) frequently results in an inability to obtain matching spatial location for all three sources⁴. Furthermore, gaps in the Satellite time series frequently prevent matching Satellite data to the same day as AIMS Insitu sampling.

The degree to which the discrete AIMS Insitu samples reflect space and time around the actual sampling sites/times is largely unknown. That is, we don't know how broadly representative the direct observations are. Consequently,

³indeed this is one of the functions of indexing metrics (see section ??)

⁴Satellite data and eReefs models are of limited value in shallow water

it is difficult to estimate how broadly to filter the Satellite and eReefs data in space and time around the AIMS Insitu sampling events in order to generate comparable data. The 'best' breadth is likely to be a compromise between data availability (time limited for Satellite and space limited for eReefs).

Figures 27 and 28 illustrate the spatial distribution of Satellite and eReefs grid cell centroid locations relative to the AIMS Insitu sampling locations. The different color spokes denote distance categories (red: <1km, purple: <5km) from the AIMS Insitu data.

The approach we took was to extract all observations within a specific series of spatio-temporal windows or neighbourhoods from which we could calculate a range of association and correspondence (such as RMSE and R^2) metrics (see Tables 8, 9, 10 & 11). Tables 9, 10 & 11 document the top 5 ranked (according to RMSE, MAE and MAPE respectively) spatio-temporal lag associations between Satellite/eReefs data and AIMS Insitu data.

Table 8: Association and correspondence metrics between Satellite/eReefs observations ($\hat{\theta}_i$) and AIMS Niskin observations (θ_i). Similar calculations can be performed on model residuals.

Metric	Description	Formulation
RMSE	Root Mean Square Error - is a measure of accuracy	$RMSE(\hat{\theta}) = \sqrt{\frac{1}{n} \sum_{i=1}^n (\hat{\theta}_i - \theta_i)^2}$
MAE	Mean Absolute Error - is a measure of accuracy	$MAE(\hat{\theta}) = \frac{1}{n} \sum_{i=1}^n (\hat{\theta}_i - \theta_i) $
MAPE	Mean Absolute Percentage Error - is a measure of accuracy expressed as a percentage of AIMS insitu samples	$MAPE(\hat{\theta}) = \frac{100}{n} \sum_{i=1}^n \frac{ \hat{\theta}_i - \theta_i }{\theta_i}$

Whilst it is well established that water quality parameters can be highly varied over time and space, even approximate degrees of spatio-temporal autocorrelation for these parameters remains largely unknown. Nevertheless, we might expect that observations from different sources collected at similar locations and at similar times should be more similar to one another than they are to more distal observations. Furthermore, whilst the absolute values derived from different sources might not be exactly the same, we should expect a reasonable degree of correlation between the sources. Given these two positions (that observations should be autocorrelated and that different sources should be correlated), we should expect that the degree of correlation between the different sources for a given measure should be strongest for observation pairs closer together in space and time.

Tables 9 – 11 tabulate the association and correspondence metrics between the AIMS insitu samples and either the Satellite or eReefs data for each Measure. Irrespective of the association metric (RMSE, MAE or MAPE), closest associations with AIMS insitu observations tend to occur at shorter spatial distances for eReefs data than Satellite data, yet the opposite is apparent for temporal lags. We might have expected that associations would be strongest proximal (in both time and space) to the AIMS insitu samples and associations to weaken in some sort of multidimensional decaying pattern with increasing separation. Such a pattern would permit relatively straight forward integration of the AIMS insitu observational data into the Satellite or eReefs layers⁵ However this is not the case and thus it is very difficult to formulate an integration routine that does more than just update a very limited number of points in space and time.

The other rationale for exploring the spatio-temporal associations between AIMS insitu data and Satellite/eReefs data is to be able to determine the optimal temporal lag and spatial distance for making comparisons of trends. Given that AIMS insitu data are in some respects considered the more accurate (albeit limited in the degree to which they more broadly represent space and time around the samples), a comparison of the general temporal trends of each source should give some idea of the relative accuracy of the sources of indirect measurements (Satellite and eReefs). Figures. 29 – 32 illustrate the temporal patterns of Chlorophyll-a, TSS, Secchi depth and NOx for each source (AIMS insitu, AIMS FLNTU, Satellite, eReefs and eReefs926) for each of the AIMS insitu sampling locations. The background fills of the site titles are colored according to water body (Red: Enclosed Coastal, Green: Open Coastal, Blue: Midshelf).

All sources of data are typically most variable at Enclosed Coastal sites and substantially less variable at Midshore sites. Moreover, the alignment of trends also appears to be substantially better at Midshore sites. Enclosed Coastal and Open Coastal sites are closer to the coasts and in particular, closer to major sources of discharge (as

⁵Having a robust and consistent pattern of spatial and temporal autocorrelation would allow us to model the expected value of AIMS insitu data at unobserved locations.

intended by the AIMS Water Quality MMP) whereby water conditions are subject to more extreme fluctuations that result in conditions varying rapidly in time and space. Moreover, these sites are likely to be in shallower water or water whose depth is relatively heterogeneous. As a result, data pooled within a 5km radius might represent a substantially different body of water than that represented by the AIMS insitu point sources. By contrast, the conditions represented within a 5km radius at Midshelf sites are likely to be more homogeneous and thereby resulting in a fairer comparison.

Notwithstanding the disparity in fairness between different water bodies as a result of how well the various sources represent spatial and temporal envelopes, it is unlikely that either the eReefs models or Satellite data are going to provide accurate estimates for Enclosed Coastal water bodies. However, the accuracy for Midshelf and Offshore are likely to be sufficient.

Table 9: Top five ranked AIMS Niskin vs Satellite/eReefs observation association metrics (RMSE: root mean square error; MAE: mean absolute error; MAPE: mean percent error; Value: regression slope, residual.RMSE: residual root mean square error, residual.MAE: residual mean absolute error, R2.marginal: R^2 marginalized over sites, R2.condition: R^2 conditional on sites) per Measure per source (Satellite, eReefs) for spatial/temporal lags. Rows ranked and filtered based on RMSE. Dist and Lag represent spatial (km) and temporal (days) lags.

5. INDEX METRICS

5.1 Theoretical framework

Each individual indicator (or sub-indicator) addresses a different aspect of the state of an ecosystem. Hence, even a modest number of (sub)indicators will yield multiple perspectives on ecosystem health. Capturing the essence of the ecosystem health or an indicator thereof, necessitates integrating (aggregating) each of these perspectives together into a single *index*. There are numerous methods that have been applied to index aggregation, the most popular of which are itemized by Fox (2013) and described and evaluated in the context of water quality indices by either Walsh and Wheeler (2012) (from the perspective of cost benefit analyses) or Whittaker et al. (2012).

5.1.1 Multivariate health indicators

Motivated by the need to integrate multiple disparately scaled ecological variables together in the absence of any normalizing information (such as benchmarks, guidelines or thresholds, see Section 5.1.2), a variety of predominantly multivariate analyses have been used in the generation of ecosystem health indices. However, Whittaker et al. (2012) cautioned that since the incorporated weights are all exclusively informed by the statistical properties of the constituent indicator data, if these statistical properties did not coincide with expert knowledge of the relative importance of the indicators, then the resulting indices are likely to be poor.

As an alternative, Whittaker et al. (2012) suggest the Malmquist index. The computational details of the Malmquist index are rather complex and since this method does not appear to have been adopted by any report cards, we will restrict our description to just a brief overview. Whittaker et al. (2012)'s proposed version of the Malmquist index calculates pairwise ratios of indicator distances from a multivariate benchmark curve. The benchmark curve (a form of indifference curve), is a multivariate curve defined by the lower boundary of a convex hull of all indicator values and is thus derived entirely from the observed data. Using simulated data with manufactured statistical complications (heterogeneity and temporal autocorrelation), Whittaker et al. (2012) demonstrated that the Malmquist index out performs indices based on principal components analysis and suggested other statistical methods would have similar shortcomings.

5.1.2 Thresholds

The absolute value of an indicator is rarely a meaningful assessment of ecosystem health assessments. Nor are the statistical properties of a time series necessarily a good basis for normalizing indicators or representing the objectives. What constitutes a 'good' or 'poor' level is likely to vary according to indicator, the ecosystem (e.g. freshwater, estuarine or marine) as well as the geographical and temporal (e.g. pre-industrial or current, seasonal) context. Another way to normalize the location (center) of indicators (if not the scale as well) that incorporates both knowledge about the ecological basis of the indicator and the objectives that they address is to express the indicators relative to *benchmarks*.

Benchmarks are typically either reference or baseline conditions (sites or historic data representing relatively low disturbance 'healthy' conditions), threshold values (ecotoxicology tolerances representing the cusp of 'unhealthy conditions) or guideline values (derived from either historical quantiles or ecotoxicology). Thresholds and guideline values are typically peer reviewed and ecologically meaningful, yet their specificity varies from local to regional, national or international standards.

Whilst a 'distance to benchmark' approach does provides some level of standardization (Connolly et al., 2013), to be useful, not only should there be some form of homogenization in what the benchmark condition represents, the polarity of the distance should be well understood (Hijuelos and Reed, 2013) and the magnitude of the distance should be commensurate with position along a disturbance gradient. That is, there should be some consistency in what it means to be above or below a benchmark, and indeed what it means to be a certain distance from a benchmark. Ideally, benchmarks should also be locally relevant (Connolly et al., 2013) and consider seasonal variability (Coates et al., 2007; Hallett et al., 2012). Indeed, in a review of the methodologies used to set benchmarks, (Borja et al., 2012) demonstrated the importance of setting appropriate benchmarks from which to assess ecosystem quality by directly linking the inability of indices to detect impacts in ecosystems to inappropriate reference conditions.

It is also important that benchmarks align with objectives in order to ensure indicators are appropriate. For example, if an objective is to maintain sustainable stocks of a particular species of fish, a benchmarks that reflect either historical numbers or the numbers present at low pressure sites do not necessarily represent the level of sustainability.

Ecological monitors have long recognized the need to express ecosystem ratings as standardized scores and in terms that are more accessible to policy makers and the general public. Whilst initial applications focused on normalizing observed measures against subjective rating curves to yield dimensionless index values on the scale of [0,1] that could be readily combined into a single understandable score or rating (e.g. Miller et al., 1986), more recent studies have explored formulations that compare observed measures to baseline, reference, objectives or guideline values (collectively, benchmarks) values (e.g. CCME, 2001; Hurley et al., 2012; Jones et al., 2013).

Connolly et al. (2013) reviewed the use of report cards for monitoring ecosystem health and tabulated the general properties of a range of methods employed across many different monitoring programs. Rather than duplicate that information here, the current intention is to provide more specific details about the algorithms used across those programs.

5.1.3 Unifying indices

The Canadian Council of Ministers of the Environment Water Quality Index (CCME WQI; CCME, 2001) incorporates comparisons to baseline based on scope (proportion of indicators that have one or more failures to meet objectives), frequency (proportion of all comparisons failing to meet objectives) and amplitude (the normalized degree to which failed comparisons exceed objectives).

$$\begin{aligned}
 F_1 &= 100 \cdot \left(\frac{\text{Number of failed indicators}}{\text{Total number of indicators}} \right) \\
 F_2 &= 100 \cdot \left(\frac{\text{Number of failed comparisons}}{\text{Total number of comparisons}} \right) \\
 F_3 &= \frac{100 \cdot E}{1 + E}; \quad E = \frac{\sum_{i=1}^n e_i}{n}; \quad e_i = z_i \cdot \left[\left(\frac{x_i}{\text{benchmark}_i} \right)^{\lambda_i} - 1 \right] \\
 z_i &= \begin{cases} 1 & \text{if ith comparison fails} \\ 0 & \text{otherwise} \end{cases}; \quad \lambda_1 = \begin{cases} 1 & \text{If } < \text{benchmark}_i = \text{fail} \\ -1 & \text{If } > \text{benchmark}_i = \text{fail} \end{cases} \\
 CCMEWQI &= 100 - \left(\frac{\sqrt{F_1^2 + F_2^2 + F_3^2}}{1.732} \right)
 \end{aligned}$$

where n is the number of comparisons.

Whilst the CCME WQI might serve its purpose in the context to which it is applied, it is unlikely to be a useful metric for any indices involving remote sensing data or indeed any situation with a reasonable large amount of data or indicators. One-third of the weighting of the metric is calculated on the proportion of indicators that failed. The more observations are collected, the more likely at least one of them will exceed the benchmark. Hence, this one-third will quickly approach a constant of 1 thereby reducing overall sensitivity. In addition, the one-third of the method that weighting on amplitude only does so with respect to failure - there is no degree of how well the data recedes the benchmark. Finally, unifying indices have very limited scope for propagating any uncertainty. Consequently, this metric of index computation will not be explored in this project.

Rather than calculate the proportion of all comparisons failing to meet objectives across all indicators (as in the frequency component of the CCME WQI), we could perform the calculation separately for each variable (measure). Whilst this formulation (**Exceedence**), is characterised by the same limitations as the above frequency component, since it is calculated separately for each variable, when aggregated together to form an overall indicator, there is greater potential for improved resolution and granularity.

5.1.4 Hierarchical indices

The CCME WQI unifies all indicators into a single index as part of the calculations. However, most other indices involve aggregating across a sets of individual indicator scores. There are numerous ways to formulate indicator scores based on deviations from a benchmark (see Table 12).

Importantly, these scores are typically calculated at the level of the observations. Most of the index formulations are relatively robust to outliers (since the scores are either on a scale that reduces the magnitude of outliers or are capped to a range) and thus aggregating together indices is likely to be more robust than calculating indices from aggregated raw data. An exception to this might be in situations where benchmarks are defined in the context of a specific spatial or temporal aggregation (such as annual mean or median value).

The Binary method expresses a comparison to benchmark values on a binary compliance scale (1: complies with benchmark, 0: fails to comply) and whilst simple to perform and understand, this method results in indices that have the potential to be either under or overly sensitive (depending on how far observed values typically are from the benchmark). For example, at one extreme (when values are close to benchmark), slight changes yield dramatic fluctuations in scores. However, when values are substantially above or below the benchmark, even modest improvements or deterioration will be undetected. This rapid 'switching' behaviour is depicted by the stepped response curve.

Note, when aggregated via means, the Binary method is identical to the Exceedence method, except that uncertainty propagation is slightly more straight forward via the Binary method.

In the State of the Great Lakes Report (EPA/EC, 1995), greater granularity is achieved via a panel of experts who classify each of six health indicators (aquatic community health, human health, habitat, contaminants, nutrients and economy) into four categories: poor, mixed/deteriorating, mixed/improving, good/restored. Similar expert rating or multi-category exceedance grading systems are employed in other report cards (e.g Tamar estuary Report Card; Attard et al., 2012) and whilst probably reasonably accurate, they are nonetheless highly dependent on the ongoing availability of a reasonably stable panel of independent experts.

The Benchmark and Worst Case Scenario method (see Table 12) employed by the Fitzroy Basin Report Card (Jones et al., 2013) reflects the degree of failure by scaling the difference between the observed values and benchmarks (20_{th} or 80_{th} percentile of long term data for values above and below the benchmark respectively) to the Worst Case Scenario values (10_{th} or 90_{th} percentiles respectively). The associated response curve demonstrates a linear decline in Score with increasing distance from the benchmark.

The Modified Amplitude method calculates the distance to benchmark on a logarithmic (base 2) scale. The base 2 logarithm represents ratios on a symmetric scale such that values that are twice and half the benchmark yield scores of the same magnitude (yet apposing signs), and has some inbuilt capacity to accommodate skewed data. The Modified Amplitude response curve illustrates how this method can be simultaneously relatively insensitive to slight fluctuations around the benchmark as well as sensitive to changes further away from the benchmark.

Contrastingly, the Logistic Amplitude method operates on a logit scale such that it is very sensitive to slight fluctuations close to the benchmark and becomes progressively less sensitive with increasing distance. This method is also automatically scaled to the range [0,1]. The steepness of the Logistic Amplitude response can also be controlled by a tuning parameter (T).

Water Quality indices (which are standardized measures of condition) are typically expressed relative to a guideline, threshold (see Table A1 on page 177) or benchmark. Of the numerous calculation methods available, those that take into account the distance from the threshold (i.e. incorporate difference-to-reference) rather than simply an indication of whether or not a threshold value has been exceeded are likely to retain more information as well as being less sensitive to small changes in condition close to the threshold.

The challenging aspect of distance (or amplitude) based index methodologies is that determination what constitutes a large deviation from a benchmark depends on the scale of the measure. For example, a deviation of 10 units might be considered relatively large of turbidity (NTU) or salinity (ppt), yet might be considered only minor for the Chlorophyll-a ($\mu\text{g/L}$). In order to combine a range of such metrics together into a meaningful index, the individual scores must be expressed on a common scale. Whilst this is automatically the case for Binary compliance, it is not necessarily the case for distance based indices.

Table 12 describes and compares the formulations and response curves of the Binary compliance method as well as a number of amplitude (distance based) indexing methods.

The Modified Amplitude and Logistic Modified Amplitude are both based on a base 2 logarithm of the ratio of observed values to the associated benchmark (see Table 12). This scale ensures that distances to the benchmark are symmetric (in that a doubling and halving equate to the same magnitude - yet apposing sign). Furthermore, the logarithmic transformation does provide some inbuilt capacity to accommodate log-normality (a common property of measured values).

By altering the sign of the exponent, the Modified Amplitude methods can facilitate stressors and responses for which a failure to comply with a benchmark would be either above or below the benchmark (e.g. NTU vs Secchi depth). Further modifications can be applied to accommodate measures in which the benchmark represents the ideal and deviations either above or below represent increasingly poorer conditions (e.g. pH and dissolved oxygen).

The raw Modified Amplitude scores are relatively insensitive to small fluctuations around a benchmarks and sensitivity increases exponentially with increasing distance to the benchmark. The resulting scores can take any value in the real line $[-\infty, \infty]$ and hence are not bounded⁶. There are two broad approaches to scaling (see Table 12):

1. Capping and scaling: The \log_2 scale can be capped to a range representing either a constant extent of change (e.g. twice and half the benchmark - a cap factor of 2) or else use historical quantiles (10th and 90th percentiles) to define the upper and lower bounds to which to cap the scale. Note historical quantiles are unavailable for the current application⁷. Thereafter, either can be scaled to the range [0,1] via a simple formula (see Table 12 III.Scaled).
2. Logistic Modified Amplitude: By expressing the scores on a logistic scale, the range of scores can be automatically scaled to range [0,1]. Moreover, this method allows the shape of the response curve to be customized for purpose. For example, the relative sensitivity to changes close or far from the benchmarks can be altered by a tuning parameter.

Rather than aggregating across sites before calculating indices, we would suggest that indices should be calculated at the site level. This is particularly important when different measures are measured at different sites. Spatial variability can be addressed via the use of a bootstrapping routine (see below). We would recommend that measurements collected throughout the reporting year be aggregated together into a single annual value. This is primarily because most water quality thresholds pertain specifically to annual averages rather than single time samples. Although it is possible to incorporate uncertainty due to temporal variability, the low sparse temporal frequency of sample collection is likely to yield uncertainty characteristics that will swamp the more interesting spatial sources of uncertainty.

Alternatively, if we relax the application of thresholds to individual observations, annual indices can be generated by aggregating observations level indices. When doing so, the Binary Compliance formulation aggregated via means will yield identical outcomes to the Exceedence formulation.

A useful metric for comparing the sensitivity of one indexing method over another is to take some representative longitudinal data and calculate indices based on the actual data as well as data that introduces progressively more noise.

Table 12: Formulations and example response curves for a variety of indicator scoring methods that compare observed values (x_i) to associated benchmark, thresholds or references values (B_i and dashed line). The Scaled Modified Amplitude Method can be viewed as three Steps: I. Initial Score generation, II. Score capping (two alternatives are provided) and III. Scaling to the range [0,1]. The first of the alternative capping formulations simply caps the Scores to set values (on a \log_2 scale), whereas the second formulation (Quantile based, where $Q1$ and $Q2$ are quantiles) allows thresholds quantiles to be used for capping purposes. Dotted lines represent capping boundaries. In the Logistic Scaled Amplitude method, T is a tuning parameter that controls the logistic rate (steepness at the inflection point). For the purpose of example, the benchmark was set to 50.

Method	Formulation	Response curve
Binary compliance	$Score_i = \begin{cases} 1 & \text{if } x_i \leq B_i \\ 0 & \text{if } x_i \text{ else} \end{cases}$	<p>The graph shows a step function. The y-axis is labeled 'Score' with ticks at 0.00, 0.25, 0.50, 0.75, and 1.00. The x-axis is labeled 'x' with ticks at 0, 25, 50, 75, and 100. A solid black line starts at (0, 1) and drops to (50, 0). A vertical dashed line is drawn at x = 50.</p>

⁶Unbounded indices are difficult to aggregate, since items that have very large magnitude scores will have more influence on the aggregation than those items with scores of smaller magnitude. Furthermore, unbounded scores are difficult to convert into alphanumeric Grades. Consequently, the Scores need to be scaled before they can be converted to alphabetical grading scale.

⁷The use of historical quantiles makes the explicit assumption that the domain of expectations (from very good to very poor) is encapsulated within the historical data. For the eReefs model data, only three years of historical data are available. This is unlikely to be sufficient to represent the full spread of what we should consider our expectations - particularly when we acknowledge that the eReefs model data do not extend back as far as the 2010-2011 floods during which water quality conditions might be expected to be lower than the years to follow.

Table I2: Report Card indexing methods, continued

Method	Formulation	Response curve
Benchmark and WCS	$Score_i = \begin{cases} 100 & \text{if } x_i \leq B_i \\ 0 & \text{if } x_i \geq WCS_i \\ \left[1.0 - \left\lfloor \frac{x_i - B_i}{WCS_i - B_i} \right\rfloor\right] \cdot 100 & \text{else} \end{cases}$	
Amplitude	$Score_i = \begin{cases} \left(\frac{x_i}{B_i}\right)^{-1} & \text{if } x_i > B_i = \text{fail} \\ \left(\frac{x_i}{B_i}\right)^1 & \text{if } x_i < B_i = \text{fail} \end{cases}$ $Score_i = \frac{100 \times Score_i}{1 + Score_i}$	
Modified Amplitude	<p>I. Raw (MAMP)</p> $Score_i = \begin{cases} \log_2\left(\frac{x_i}{B_i}\right)^{-1} & \text{if } x_i > B_i = \text{fail} \\ \log_2\left(\frac{x_i}{B_i}\right)^1 & \text{if } x_i < B_i = \text{fail} \end{cases}$ <p>II. Fixed caps (Fold=2; [0.5,2]) (Fold=4; [0.25,4])</p> $Score_i = \begin{cases} \log_2(1/2) & \text{if } Score_i < -1 \\ \log_2(2/1) & \text{if } Score_i > 1 \\ Score_i & \text{otherwise} \end{cases}$ <p>III. Quantile/extremes based caps ([15,170])</p> $Score_i = \begin{cases} \log_2\left(\frac{Q1}{B_i}\right)^{-1} & \text{if } x_i < Q1 \\ \log_2\left(\frac{Q2}{B_i}\right)^{-1} & \text{if } x_i > Q2 \\ Score_i & \text{otherwise} \end{cases}$ <p>III. Scaled (Fixed: Fold=2)</p> $Score_i = \frac{Score_i - min(Score_i)}{max(Score_i) - min(Score_i)}$	

Table I2: Report Card indexing methods, continued

Method	Formulation	Response curve
Logistic	Raw	
Scaled	$Score_i = \begin{cases} \log_2(\frac{x_i}{B_i})^{-1} & \text{if } x_i > B_i = \text{fail} \\ \log_2(\frac{x_i}{B_i})^1 & \text{if } x_i < B_i = \text{fail} \end{cases}$	
Modified Amplitude	$Score_i = \frac{1}{1+e^{Score_i-T}}$	
Logistic	Raw $Score_i = \begin{cases} \frac{1}{1+e^{T \cdot (x_i/B_i)}} & \text{if } x_i > B_i = \text{fail} \\ \frac{1}{1+e^{-T \cdot (x_i/B_i)}} & \text{if } x_i < B_i = \text{fail} \end{cases}$	

Whilst the state of the water (or other environmental condition) might be of interest in its own right, it might also be of interest from the perspective of the ecosystem supported by the water. For example, turbidity might be considered to provide important insights into the light availability within the ecosystem. As such, the variability in light availability (turbidity) might be a more influential ecological driver/pressure than the exact light level within any given time frame. Furthermore, sustained conditions might be more influential than rapidly fluctuating conditions. For example, two time windows could experience the same turbidity average and variance, yet these summaries could manifest from very different fluctuation patterns (one experiencing rapid fluctuations, and the other experiencing sustained periods of contrasting conditions).

One index that captures the pattern of fluctuations could be based on a metric that expresses the number of consecutive days in which a threshold has been exceeded as a proportion of number of days in the time window (e.g. 365 days).

$$Score_i = 1 - (n_i/N_i)$$

where n_i is the maximum number of consecutive time units in which $x_i > B_i$ and N_i is the number of time units in the i^{th} spatio-temporal window.

Unfortunately, such a formulation imposes some relatively difficult requirements on the data. Firstly, the time series within each window must be complete (no gaps), otherwise it is difficult to assess N_i . This requirement limits its use to only the eReefs modelled data as the Satellite data, AIMS insitu and AIMS FLNTU data have substantial time gaps. Secondly, as the formulation is based on summing up exceedences, it is likely to be as susceptible to the recognised insensitivities associated with binary compliance. Indeed, these sensitivities may well be further amplified. Furthermore, it is not responsive to the magnitude of exceedence.

The next section will explore the performance of the following index formulations:

- Binary compliance (Binary)
- Exceedence - proportion of observations exceeding the threshold (on large datasets, this will converge with Binary compliance (Exceed))
- Maximum duration of exceedence (Max_Duration)
- Modified Amplitude (MAMP)
- Fixed Modified Amplitude (fMAMP)
- Fixed Scaled (x2,1/2) Modified Amplitude (fsMAMP)
- Fixed Scaled (x4,1/4) Modified Amplitude (fsMAMP4)

5.2 Index sensitivity

The sensitivity of a metric can be gauged by either:

- Quantitative exploration of the relationships between the metric and gradients of the underlying conditions that the metric should respond to. This approach requires very well defined gradients as well as a clear understanding and measures of what constitutes a relationship. By optimizing the metric(s) to these gradients, this approach has the potential to bias outcomes towards these gradients at the expense of generality to other gradients.
- Have experts (or end users) qualitatively gauge the outcomes of different metrics against expected trends and patterns. That is, do the outcomes align with end user expectations. Although this approach is equally subjective and potentially biased as the quantitative exploration, it does not necessitate formulating statistical cutoffs and associated artifacts.
- Explore the behaviour and characteristics of the metric when calculated on data simulated to represent a range of scenarios (altering location and spread). Whilst this approach will not necessarily select the 'best' metric, it does permit identification of the limitations and assumptions associated with different metrics.

The above approaches are not mutually exclusive. The current project will explicitly explore sensitivity via a simulation approach, yet will also encourage feedback as to whether final outcomes align with expectations. It should be noted that the current project is limited in sources of data and measured properties. A metric is purely a re-expression of data in order to enhance or highlight a signal. If the underlying data do not contain the expected signal, a signal will likewise be absent from any metrics.

To explore the performance and sensitivity of the various index computations for a range of data scenarios, data were simulated from Gamma distributions varying in mean (relative to a threshold) and variance and sample size. The Gamma distribution is parameterized by two shape parameters that can be expressed in terms of mean and variance ($\text{Gamma}(\mu^2/\sigma^2, \mu/\sigma^2)$).

For each threshold value ($GL = 0.1, 0.2, 0.5, 1, 1, 10, 100$) and sample size ($R=10, 100, 1000$), a set of 28 data scenarios where simulated (see Table 13 so as to represent a full spectrum of possible sampling outcomes. For each threshold/sample size and set combination, indices were calculated and aggregated for the simulated data. The extremes of these combinations are presented in Figures 33, 36 and 37, a more extensive set of Figures are in Appendix ???. For the set of simulations, the smaller the threshold, the more variable the samples relative to the threshold. Within each threshold, the set of 28 scenarios thereby represent combinations of varying mean and relative variability.

Table 13: Index performance and sensitivity data scenarios. Data in each group are drawn from Gamma distributions whose parameterizations are based on a mean and variance. In each case the mean is some multiple of the threshold (GL) value. Multiples of threshold that are less than 1 result in data with greatest density below the threshold value. Lower variances result in less varied data.

Grp	Mean	SD	Grp	Mean	SD	Grp	Mean	SD	Grp	Mean	SD

Figure 33: Simulated data and associated indices for threshold of 0.1 and very large sample sizes ($R=1000$). Samples represent high variability relative to threshold.

As expected, indices decline with increasing values relative to the threshold (as would be the case for Chl-a or TSS) with a generally linear response being the attribute sought in our specific context. Testing the responses of indices to various combinations allowed the identification of the most appropriate and robust index calculation method.

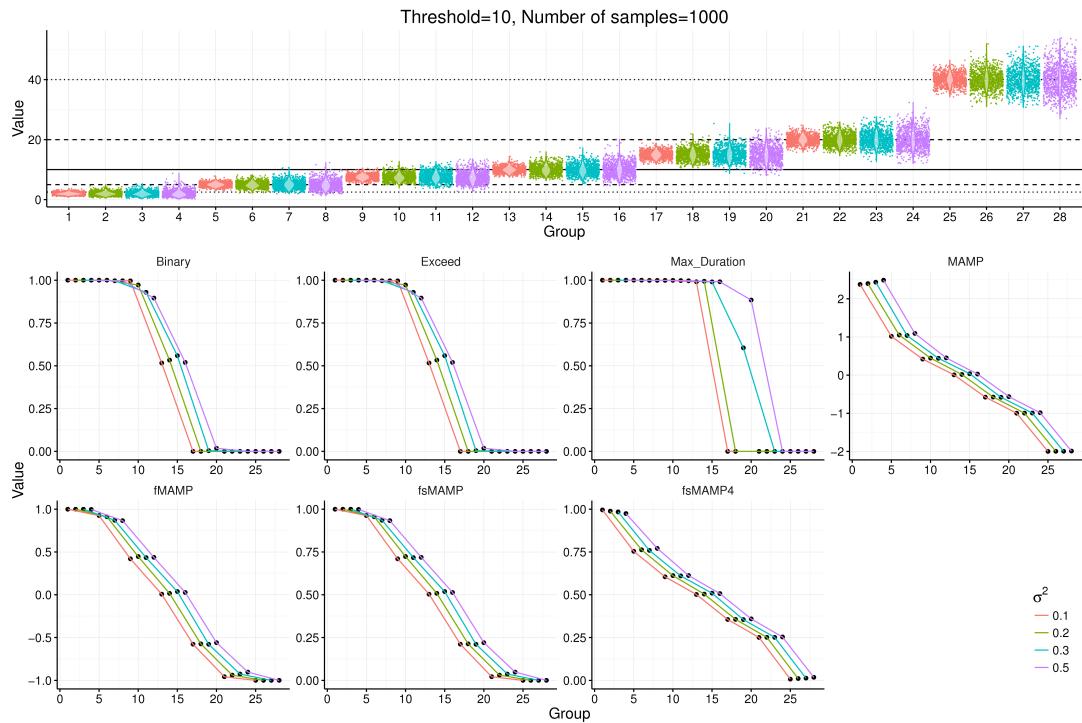

Figure 34: Simulated data and associated indices for threshold of 10 and very large sample sizes (R=1000).

When the number of samples and the relative sample variability is very large (e.g. fig. 33), with the exception of the maximum duration of exceedance and the uncapped and unscaled modified amplitude (MAMP) methods, the different index calculation methods behave very similarly. However, as the variability of the samples declines relative to the threshold (e.g. compare figs. 33, 34 and 35), such that observations are predominantly within twice/half the threshold value, and data is predominantly distributed between the threshold value binary or frequency of exceedance methods both increasingly become simultaneously overly and under sensitive. The response curve of these metrics becomes less linear, whereas the linearity of the other metrics is maintained for a greater span of observation means. This is further exacerbated by small sample sizes (see fig.37).

Over all of the scenarios, the fsMAMP4 (Modified Amplitude capped at four times/quater of threshold values) appears to be as linear or more linear than the fsMAMP (Modified Amplitude capped at twice/half), particularly as relative variability declines. However, the cost of this extended range of sensitivity, is that it is predominantly more sensitive at the extremes and less so (at least compared to fsMAMP) towards the mid-region (corresponding to values close to the threshold). Arguably, it is more desirable for an index to be most sensitive around the threshold (unless there is substantial uncertainty about the threshold value) and become progressively less sensitive at increasing distance from the threshold - the binary and exceedence metrics are the extreme cases of this.

The fixed capped modified amplitude (fsMAMP) index was considered the 'best' compromise between consistent sensitivity throughout the range of scenarios and the nature of data presented in exploratory data analyses (see Section ??). It should be noted that it is possible to modify the fsMAMP index metric to facilitate caps based on historical, biological or ecological parameters. It is also possible to define these parameters (an upper and lower capping) at any spatial/temporal/measure level so as to potentially build indices that are optimized for each measure. Such an exercise requires extensive expert knowledge to define and justify each of the parameters and is beyond the scope of the current project.

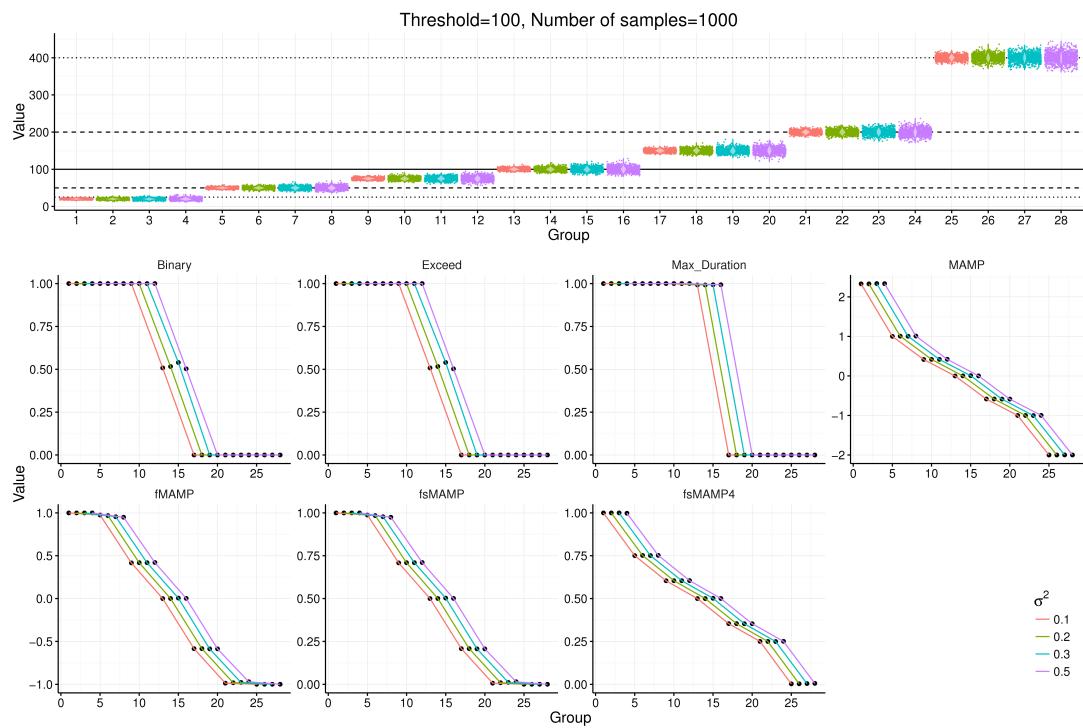

Figure 35: Simulated data and associated indices for threshold of 100 and very large sample sizes ($R=1000$).

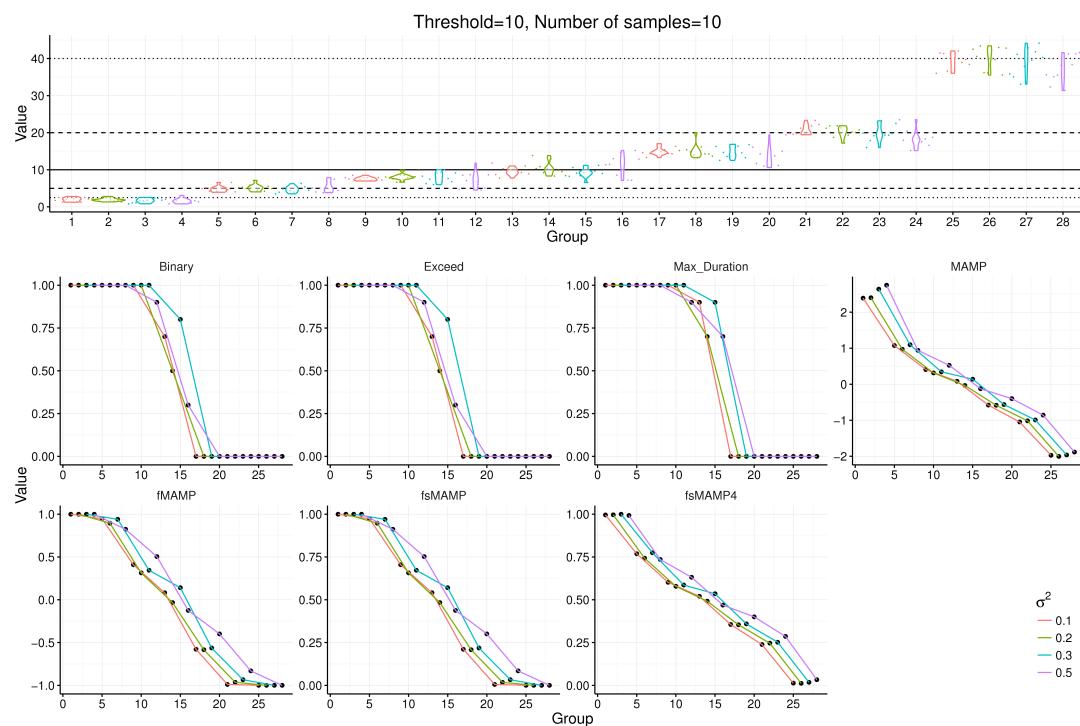

Figure 37: Simulated data and associated indices for threshold of 10 and small sample sizes ($R=10$).

5.2.0.1 *Summary of simulation index sensitivity exploration*

- Indices decline with increasing values relative to the thresholds (and for a given variability)
- Indices increase with increasing variability (since in Gamma distributions, this results in more values towards lower end)
- when R is very large, the different indicators behave similarly (except Max_Duration and MAMP)
- MAMP is more susceptible to outliers

5.3 Index explorations

Before data can be combined and aggregated across the various Sources (AIMS insitu, AIMS FLNTU, Satellite, eReefs and eReefs926) and Measures (Chlorophyll, TSS, Secchi depth and NOx), it is important that we evaluate the likely usefulness of each Source/Measure combination. For example, a Measure or Source that does not vary in both time and space is not considered very informative parameter.

Although an exploration of the patterns of spatial and temporal variation of the raw data does offer some insights into the usefulness of a parameter, it is variation in relation to expectations (thresholds) that are likely to be of greatest utility. For example, a parameter might vary substantially in time and or space and yet always be well above (or below) the threshold. In this situation (despite the apparent variability), with respect to the expectation domain, there is very little (if any) variability and thus the realised utility of the parameter is low (or else the threshold is inappropriate for the particular measure to which it is being applied).

Different parameters are measured on different scales or else have different natural background levels. Since variability (for example variance) is dependent on scale, parameters measured in larger units will typically exhibit more variability in absolute terms. Hence, in order to compare the relative utility of different parameters, it is necessary to either express variation relative to scale (such as coefficient of variation) or standardize the parameters. The scaled hierarchical index formations of Section 5.1.4 (such as Binary, fsMAMP, fsMAMP4 and logistic MAMP) are all a form of standardization which yeild scores on scales that are all bound [0,1].

The following three subsections will provide information to assist in the selection of:

- which Index formulation to adopt
- which Sources of data to use
- which Measures to include

5.3.1 Indices

Theoretical sensitivity investigation suggested that the fixed capped (half/twice threshold) Modified Amplitude (fsMAMP) is likely to be the best compromise between under and over sensitivity given the patterns of variance observed across and between the various Sources (AIMS insitu, AIMS FLNTU, Satellite, eReefs and eReefs926) and Measures (Chlorophyll, TSS, Secchi depth and NOx). The alternate approach is to explore and compare the patterns of the various index formulations in the context of both the raw collected data and expert expectations. Broadly speaking, we might expect that many water Quality parameters improve across the shelf with increasing distance from coastline. We might also expect some latitudinal patterns in which water quality generally improves along a south-north gradient with interruptions coinciding with outflow of major rivers.

To explore how the raw data are transformed into the various indices, it is useful to pair up 'before' and 'after' figures. Again, for the sake of brevity, we will focus on the same data that featured in Figure 9 (Chlorophyll-a from Wet Tropics, Open Coastal). Figures 38 – 42 illustrate the associations between the site means (subfigure a) and three of the major index candidates (b: Binary, c: fsMAMP and d: fsMAMP4) for each of the Sources of data (AIMS insitu, AIMS FLNTU, Satellite, eReefs and eReefs926). In these figures, purple and blue lines represent annual means and within year Generalized Additive Model (Wood, 2006) respectively and help highlight inter- and intra-annual variation⁸.

Similar figures for the other Measures (Total Suspended Solids, Secchi Depth and NOx) for the Dry Tropics Midshelf zone are presented in Appendix Figures C97–C142.

Inter and Intra annual variation is greatest in the Binary index method for each data Source⁹. Whilst this method does illustrate sensitivity, the values of the index do not contain any context about the magnitude of values relative to the threshold. That is, it is not possible to distinguish situations in which all observations are just under (or over) the threshold from when they are substantially under (or over) the threshold. In this way, the index has the potential to be under-sensitive to magnitude, yet very sensitive to change around the threshold. For each of the Sources (except AIMS insitu for which data are too sparse), the relative magnitude of fluctuations in the Binary index (subfigure b) appears to be substantially greater than the relative magnitude of fluctuation in the observed data (subfigure a). These patterns of relative variability might imply that the Binary index is over-sensitive.

⁸GAMs not performed for AIMS insitu data due to a lack of data over which to estimate splines

⁹this pattern also persists across all Zones (Region/Water body) and Measures - although other Measures and Zones not provided here to reduce space.

By contrast, the fsMAMP4 (capped at four times and one-fourth threshold, subfigures d) could be interpreted as under-sensitive - particularly for the Satellite data (which has highly variable observations). The fsMAMP (twice/half threshold) appears to be in between these two extremes and thus could be considered a reasonable compromise between over and under sensitivity.

Spatial representations for Wet Tropics Open Coastal Chlorophyll-a (figs. 43 – 46) and Dry Tropics Midshelf Chlorophyll-a (figs. 47 – 51) offer similar assessments - that fsMAMP provides a reasonable compromise between the potentially under and over sensitive fsMAMP4 and Binary formulations. Similar representations for Total Suspended Solids, Secchi Depth and NOx are presented in Appendix Figures C122 – C143

Time series of annually aggregated observations and associated annually aggregated indices (figs. 52 – 56) provide simplified representations of the overall spatio-temporal patterns. As with the temporal and spatial representations, the fsMAMP index consistently manifests between the Binary and fsMAMP4 formulations.

5.3.2 Sources

Typically, the major aspects of a property like water quality are not directly measurable. Properties such as productivity, water clarity, nutrients, pesticides etc encapsulate a set of underlying conditions and yet themselves are not directly measurable. Directly measurable properties (such as Chlorophyll-a, total suspended solids etc) thus act as proxies for the more broader properties. As directly measurable entities, many of these measures have long monitoring histories and there are at least some understanding of the ecological role of these measures.

A major advantage of remote sensing and modelling products in the context of environmental monitoring is that they provide substantially greater spatial and temporal coverage. However, the majority of the parameters yielded from these tools are algorithmic approximations of traditional measures. Consequently, in the context of water quality, they produce proxies of proxies.

The current project has access to a variety of sources of water quality monitoring data (see Section ??) ranging from sparse, yet vigorous direct in situ measurements (AIMS insitu) and temporally rich, spatially sparse AIMS FLNTU logger data through to spatio-temporally extensive, yet patchy remote sensing MODIS Satellite data and multiple versions of eReefs modelled data. These different sources of data are likely to provide estimates of the parameters that differ in both location (such as mean) as well as scale (variability).

Whilst it is beyond the scope of the current project to undertake a full evaluation of the accuracy, robustness and reliability of each of these sources, the indexed data permit us to explore and compare the spatio-temporal patterns of each data source. In particular, we can focus on sensitivity as suggested by variability in spatio-temporal patterns of indices of each data source and whether these patterns are consistent with expert expectations.

It is reasonable to expect that since the AIMS insitu data are the most direct measures, they would be the most accurate of all the sources, however it is also likely that these observations only represent conditions over a very restricted space and time. The AIMS insitu data are predominantly the limited spatial coverage of the AIMS insitu data that limits its utility as input into a water quality metric for the entire Great Barrier Reef.

A motivating inspiration for this project was the perceived insensitivity of the Satellite data source and aspirations to improve the sensitivity of the water quality metric as a whole. It was hoped that the introduction of eReefs modelled data would result in a metric that yields patterns that are more consistent with assumed trends.

Figures 57 – 60 contrast the broad spatial and temporal patterns in aggregated fsMAMP Chlorophyll-a, TSS, Secchi depth and NOx indices. Within a zone (Region/Water body), the Satellite data (Remote sensing) are substantially less varied than the other sources. Obvious deviations in trajectory are only really apparent for the Open Coastal areas (although not for Cape York). Moreover, while the Satellite indices are suggestive of a cross-shelf (West to East) increase in water quality, this mainly occurs between Open Coastal and Midshelf and there is little (if any) consistent South-North water quality increase.

The AIMS insitu data result in the most sensitive metrics. However, the temporal deviances in data (and thus indices) could be exaggerated by the proximal location of AIMS insitu sites relative to sources of major river discharge. Thus, this sensitivity could be artificially inflated and is unlikely to be unrepresentative. Moreover, the AIMS insitu data are restricted to just a subset (5/18) of the zones of interest.

Surprisingly, there is relatively little correspondence in trajectories between AIMS insitu and AIMS FLNTU logger data. These differences could be due either to differences in sampling designs (AIMS insitu have additional sites and thus represent a different spatial domains, AIMS FLNTU have substantially greater temporal coverage and thus are potentially more representative over time) and could also reflect direct (AIMS insitu) vs indirect (AIMS FLNTU) nature of the measurements. Either way, it is difficult endorse either of these sources as a primary data source on which to construct GBR wide Water Quality metrics.

The broad spatial pattern of both eReefs and eReefs926 appear to follow the overall expectations of South - North and West - East gradients¹⁰, with Chlorophyll-a typically increasing from S to N and W to E - more so for eReefs926 than eReefs. Unfortunately it is difficult to assess the sensitivity of temporal patterns in eReefs and eReefs926 data sources due to their relatively short availability windows. In particular, it is inconvenient that neither eReefs source extend back to the 2010–2011 wet years to provide some form of qualitative calibration.

Underlying alterations in the eReefs biogeochemical model have resulted in some relatively large changes for each of Chlorophyll-a, Secchi depth and NOx and evaluating the causes of these differences is beyond the scope of the current study.

¹⁰less obvious for TSS and NOx

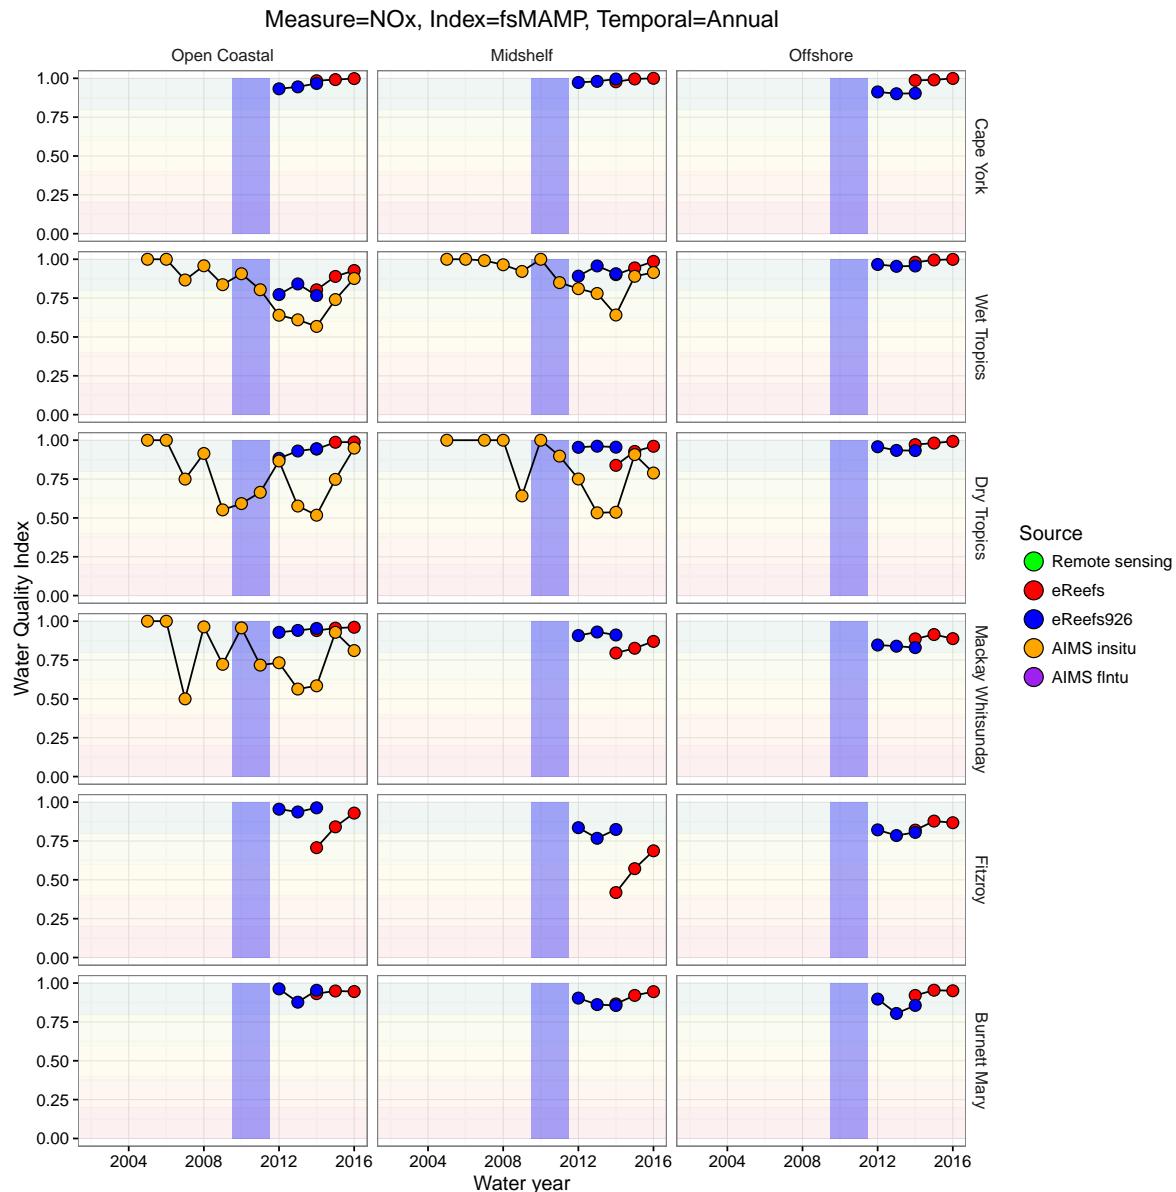

Figure 60: Time series of fsMAMP NOx index scores by zone for each data source. The blue vertical bar spans from mid 2009 to mid 2011.

5.3.3 Exploration of Measures

A Water Quality Index should attempt to reflect multiple properties of the underlying water bodies. For example, Water Quality could be characterized by combinations of Productivity, Water clarity, Nutrients, Toxicants etc. In turn, each of the above Sub-indicators, can be characterized by actual measurable properties (such as Chlorophyll-a, Total Suspended Solids, Total Nitrogen etc).

Typically, a Water Quality index is limited to what measurable properties are available and have appropriate guidelines (thresholds). The spatial extent of the current application of Water Quality metrics limits the Measures to Chlorophyll-a, Total Suspended Solids, Secchi Depth and NOx (Nitrite + Nitrate). Temporal series of the individual Measures for each Zone (based on fsMAMP of eReefs data) are presented in Figure 61.

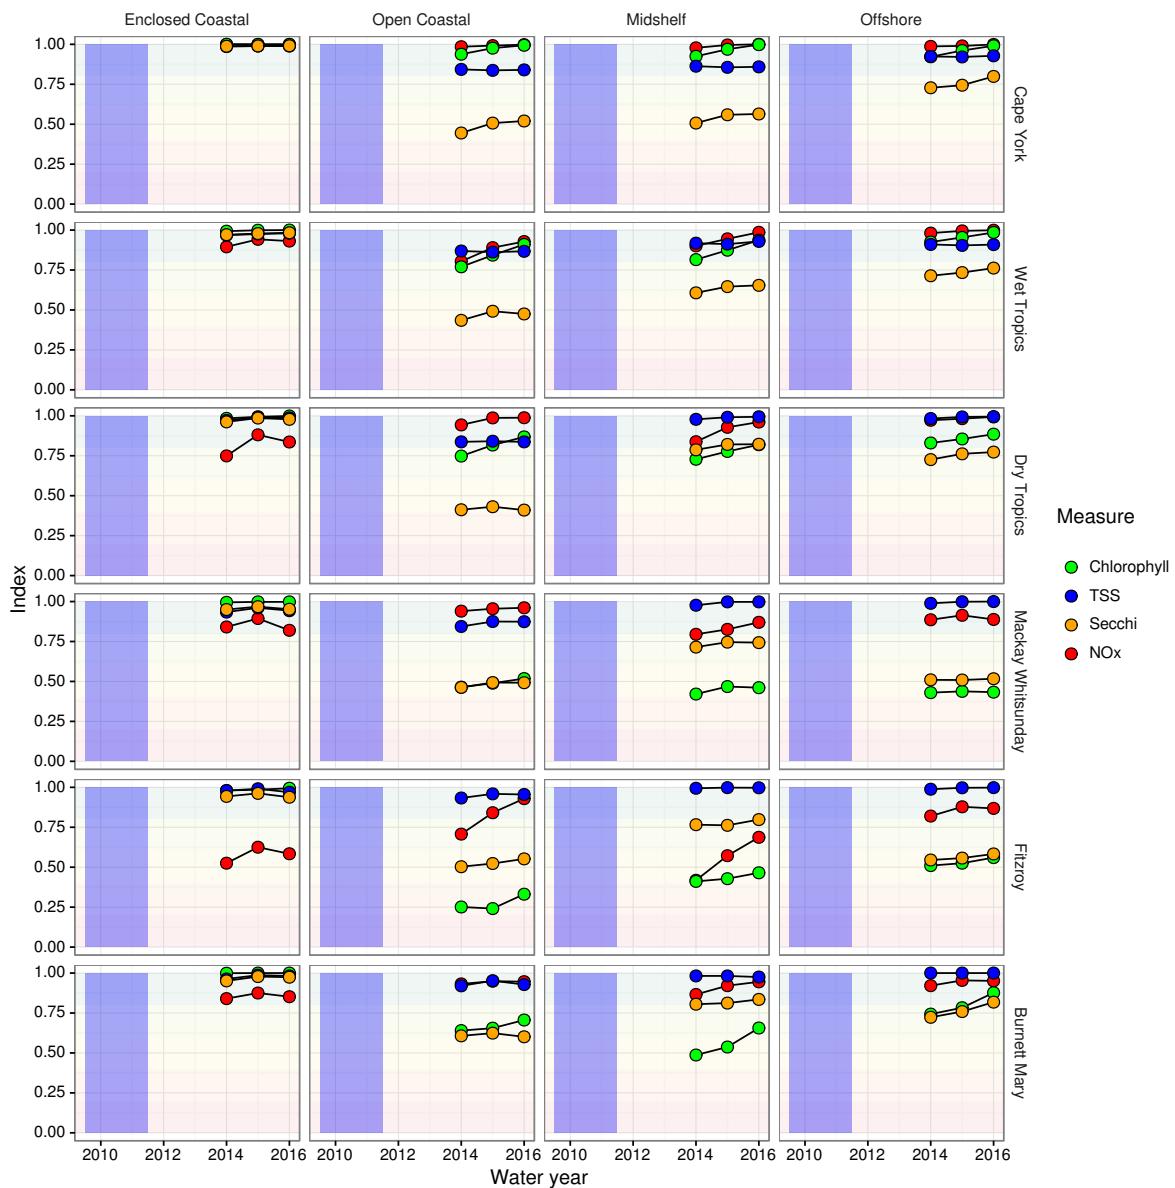

Figure 61: Time series of eReefs fsMAMP index scores by zone. The blue vertical bar spans from mid 2009 to mid 2011.

These four Measures can be placed in a aggregation hierarchy such as depicted in Table 14.

Table 14: Hierarchical association between Measures, Sub-indicators and Indicators.

Measure	Sub-indicator	Indicator
Chlorophyll-a	Productivity	Water Quality
Total Suspended Solids	Water Clarity	Water Quality
Secchi Depth	Water Clarity	Water Quality
NOx	Nutrients	Water Quality

Nevertheless, the reliability and utility of each of these Measures are not necessarily equal. A number of candidate Measure combinations¹¹ are considered (see below). The contributions of each Measure to the corresponding Water Quality Indicator Scores (based on the hierarchy presented in Table 14) are:

- Chlorophyll-a (1/3), TSS ($1/2 \times 1/3 = 1/6$), SD ($1/2 \times 1/3 = 1/6$) and NOx (1/3)
- Chlorophyll-a (1/3), TSS ($1/2 \times 1/2 = 1/4$), SD ($1/2 \times 1/2 = 1/4$)
- Chlorophyll-a (1/2), SD (1/2)
- Chlorophyll-a (1/2), TSS (1/2)

For each candidates, eReefs data with fsMAMP formulations are presented (see Figure 62).

Water Quality Indicator Scores based on candidate combinations that include either all of Chl, TSS, SD and NOx or just Chl and TSS are considered very similar. Generally, Water Quality Indicator Scores are substantially lowered by the inclusion of Secchi Depth, the severity of which depends on the degree of dilution by other Measures.

¹¹These effectively act as weights

5.4 Summary of recommendations

6. HIERARCHICAL AGGREGATIONS

6.1 Theoretical framework

To facilitate the integration of additional input Measures into the report card scores (such as additional Physical or Chemical), or even additional Sub-indicators (such as sediment metals, aquaculture yields etc), we can define a hierarchical structure in which Measures (such as Chlorophyll-a, NOx, sediment aluminum and yield etc) are nested within appropriate Sub-indicators. In turn, these Sub-indicators are nested within Indicators.

By progressively abstracting away the details of the Measures and Sub-indicators, a more focused narrative can be formulated around each level of the hierarchy. For example, when discussing the current state (and trend in state) of the Water Quality Indicator, rather than needing to discuss each individual constituent of Water Quality, high-level Grades are available on which to base high-level interpretations. More detailed explorations are thence revealed as required by exploring the Grades at progressively finer scales of the hierarchy. Moreover, the hierarchical structure offers great redundancy and thus flexibility to add, remove and exchange individual measures.

Similar arguments can be made for a spatial hierarchy in which Sites are nested within Zones which in turn are nested within the Whole GBR.

The purpose of aggregation is to combine together multiple items of data. For Nesp 3.2.5, the report card is informed by a triple hierarchical data structure in which Daily observations are nested within Seasonal and Annual aggregates, Measures are nested within Sub-indicators which are nested in Indicators and Sites are nested within Zones (see Figure 74).

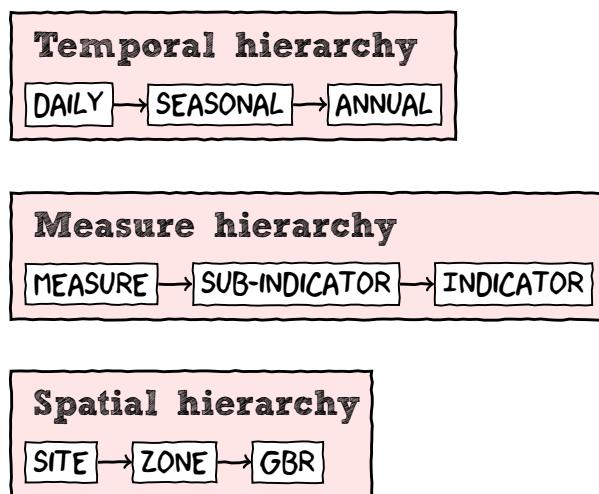

Figure 74: Temporal, measure and spatial aggregation hierarchy

Although the triple hierarchy (temporal, Spatial and Measurement), does offer substantial redundancy and power advantages, it also introduce the complexity of how to combine the hierarchies into a single hierarchical aggregation schedule. Table 15 (a fabricated example), illustrates this complexity for aggregating across Spatial and Measure scales when data availability differs. This simple example demonstrates how different aggregation schedules can result in different Zone Indicator scores:

- calculating Zone 1 Indicator Score as the average of the Site level Water Quality Scores prioritizes that the Zone 1 Indicator Score should reflect the average of the Water Quality Indicator Scores for the Site. This routine will bias the resulting Zone 1 Water Quality Indicator Score towards Sub-indicators represented in more Sites. The current MMP sampling design is unbalanced (some Zones have more Sites than others and not all Measures are observed in all Sites), and there is no guarantee that the design will be maintained over time. If for example, Chemical Measures were not available for certain Zones, then the Whole GBR Water Quality Indicator Score will be biased towards Water Clarity Sub-indicators.
- calculating Zone 1 Water Quality Indicator Score as the average of the Zone 1 level Sub-indicator Scores prioritizes equal contributions of Sub-indicators to the Indicator Score at the expense of being able to relate Zone 1 Scores to the corresponding Site Scores.

The above becomes even more complex when the temporal dimension is included..

Table 15: Fabricated illustration of the discrepancies between total means (i.e. Zone I Indicator Score) generated from row means (Site Sub-indicator Scores) and column means (Zone I Sub-indicator Scores).

Site	Sub-indicators		Indicator
	Water Clarity	Nutrients	
1	5	2	3.50
2	6		6.00
3	6	4	5.00
Zone I	5.67	3.00	X

If X (mean) is calculated from the three row means = 4.83

If X (mean) is calculated from the two column means = 4.33

An additional complication is how the different hierarchies integrate together. Specifically, what level of data should be aggregated first and at what point do the aggregations of one hierarchy feed into other hierarchies. For example, should observations first be aggregated from Daily to Seasonal or Annual, then aggregated from Site level to Zone level and then finally aggregated from Measure to Indicator? Some possible configurations are presented in Figure 75.

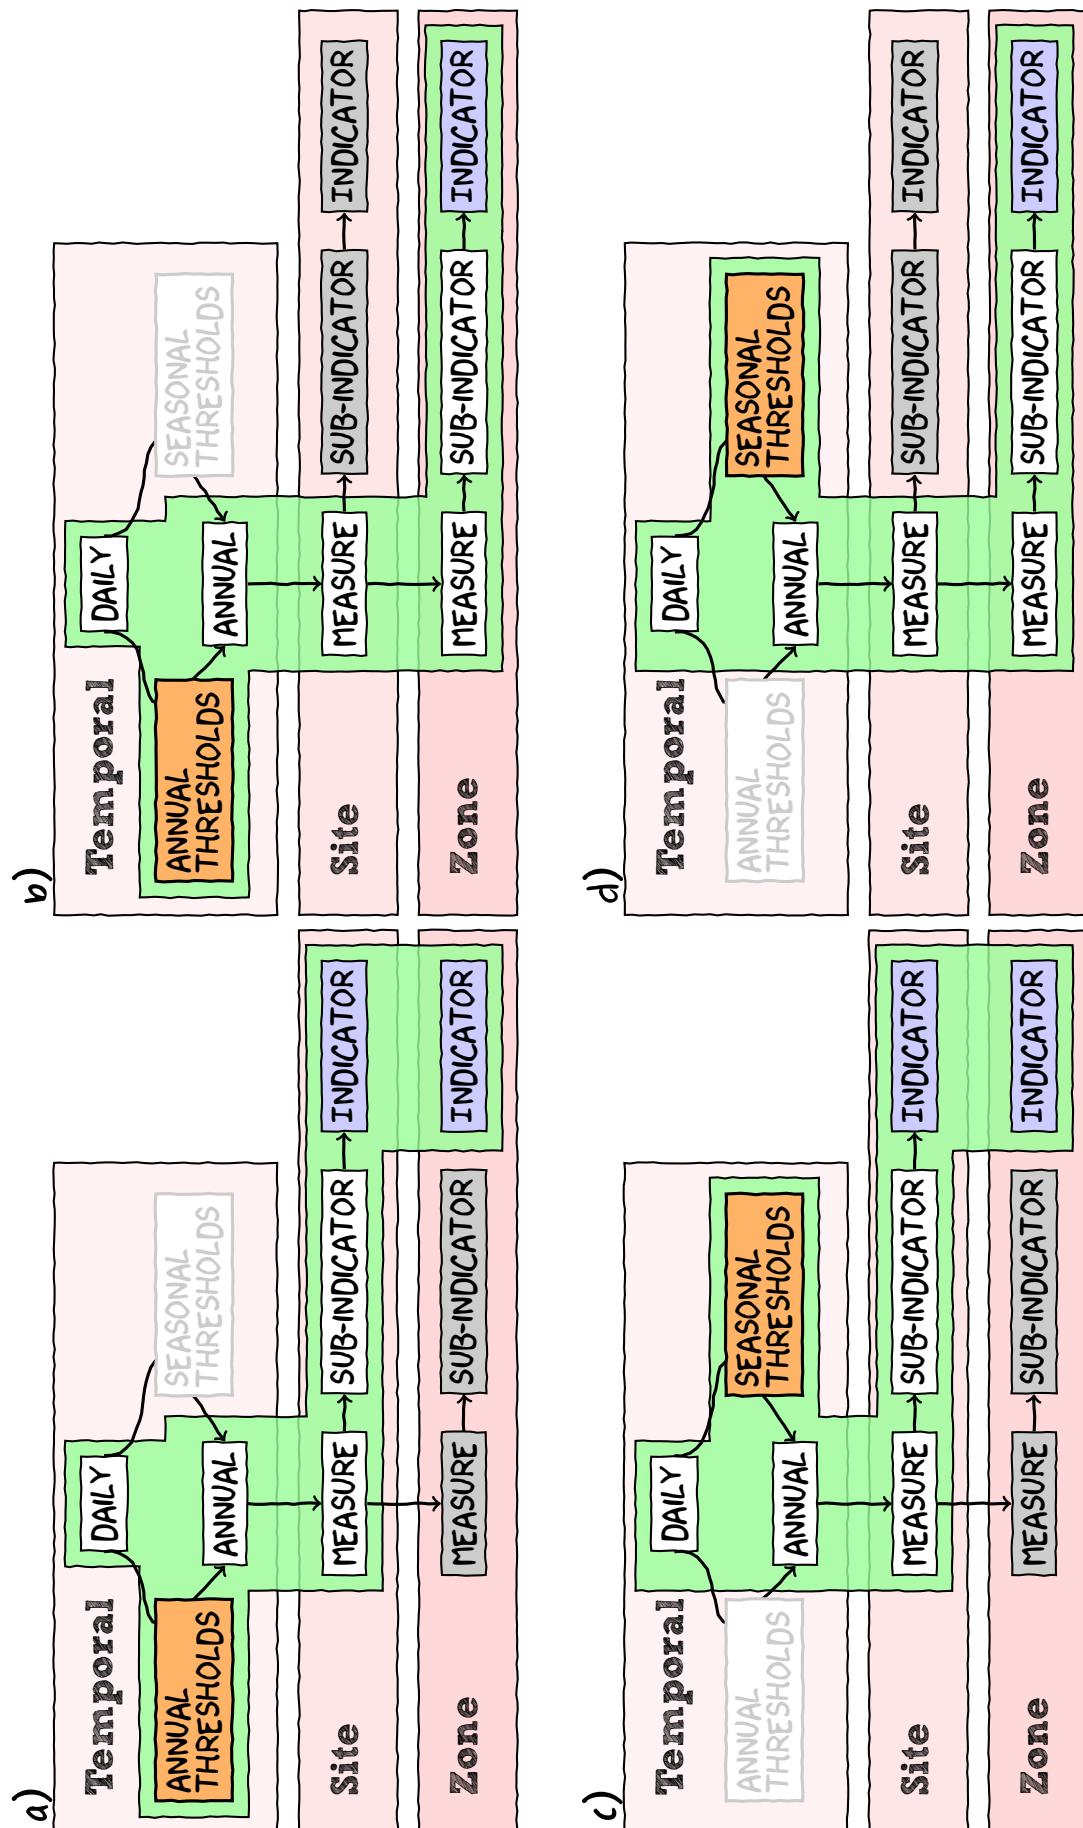

Figure 75: Schematic illustrating four possible aggregation routines through the combination of Temporal (Daily, Seasonal and Annual), Spatial (Site, Zone) and Measure (Measure, Sub-indicator, Indicator) nodes of the triple hierarchical aggregation routine associated with the GBR Report Card. Aggregation directions between nodes are signified by arrows and the main aggregation pathway through the routines is illustrated by the green polygon.

To maximize information retention throughout a series of aggregations, it is preferable to aggregate distributions rather than single properties of those distributions (such as means). The simplest way to perform a hierarchy of aggregations is to interactively calculate the means (or median) of items (means of means etc). At each successive aggregation level only very basic distributional summaries (such as the mean and perhaps standard deviation) are retained, the bulk of upstream information is lost. Alternatively, more complex methods that involve combining data or probability distributions can be effective at aggregating data in a way that propagates rich distributional properties throughout a series of aggregations.

Importantly, if the purpose of aggregation is purely to establish a new point estimate of the combined items, a large variety of methods essentially yield the same outcomes. On the other hand, if the purpose of aggregation is also to propagate a measure of uncertainty or confidence in the point estimate through multiple hierarchical levels of aggregation (as is the case here), then the different methodologies offer differing degrees of flexibility and suitability.

Hierarchical aggregations are essentially a series of steps that sequentially combine distributions (which progressively become more data rich). The resulting distribution formed at each step should thereby reflect the general conditions typified by its parent distributions and by extension, each of the distributions higher up the hierarchy.

Numerous characteristics can be estimated from a distribution including the location (such as mean and median) and scale (such as variance and range). For the current project, the mean and variance were considered the most appropriate¹² distributional descriptions and from these estimates Grades and measures of confidence can be respectively derived. Hence the numerical summaries (mean and variance) at any stage of the hierarchical aggregation are a byproduct rather than the sole property of propagation.

6.1.1 Bootstrap aggregation

Although some of the items to be aggregated together might initially comprise only a few values (or even a single value), it is useful to conceptualize them as continuous distributions. For example, when aggregating multiple Measures (such as all Water Quality Chemicals) together to generate a (Site level) Sub-indicator average, each Measure in each Site can be considered a distribution comprising the single Score for that Measure. Aggregation then involves combining together the multiple distributions into a single amalgam (by adding the distributions together, see Figure 76). Similarly, when aggregating at the *Indicator* level across Site to generate Zone summaries for each *Indicator*, Site distributions are respectively added together to yield a single distribution per Zone.

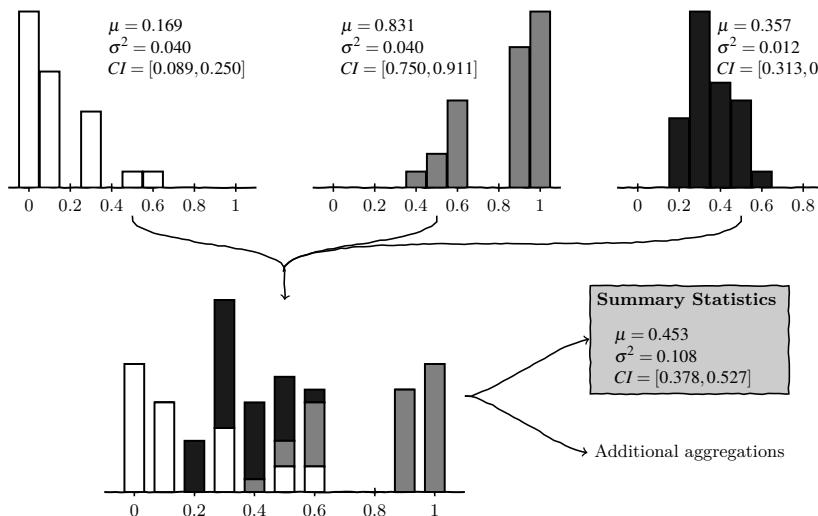

Figure 76: Illustration of Bootstrapped aggregation of three distributions. Simple summary statistics (mean, variance and 95% confidence interval presented for each distribution).

If the distributions being aggregated are all proportional distributions (e.g. density distributions), adding them altogether is trivially simple. However, if, rather than actual distributions, the items to be aggregated are ac-

¹²The aggregations typically involve some Measures with a small number of unique observations (and thus indices) and thus means and variances provide greater sensitivity than medians and ranges. Moreover, the indexing stage effectively removes outliers and standardizes the scale range thereby reducing the need for robust estimators.

tually just small collections of values (as is the case for many of the discrete Measures here) or even large, yet unequally populous collections of values (as could be the case for Continuous Flow Monitoring with missing or suspect observations), then simply aggregating the distributions together will result in amalgams that are weighted according to the size of the collections (larger collections will have more influence). For example, if we were aggregating together three Zones (to yield Whole GBR estimates), one of which comprised twice as many Sites, simple aggregation of distributions would result in a distribution that was more highly influenced by the Zone with the more Sites. Similarly, when aggregating from the level of Sub-indicator to the level of Indicator, the resulting Indicator would be biased towards the Sub-indicator with the most Measures. Whilst this may well be a useful property (e.g. stratified aggregation), it may also be undesirable.

Bootstrapping is a simulation process that involves repeated sampling (in this case with replacement) of a sample set with the aim of generating a bootstrap sample from a distribution. This bootstrap sample can be used to estimate the underlying probability distribution function that generated the data as well as any other summary statistics. Importantly, bootstrapping provides a way to generate distributions that are proportional and thus un-weighted by the original sample sizes thereby facilitating un-weighted aggregation¹³. Bootstrapped distributions can be aggregated (added together) to yield accumulated child distributions that retain the combined properties of both parents (see Figure 76). As a stochastic process, repeated calculations will yield slightly different outcomes. Nevertheless, the more bootstrap samples are collected, the greater the bootstrap distributions will reflect the underlying Score distribution and provided the number of drawn samples is sufficiently large (e.g. 10,000 re-samples), repeated outcomes will converge.

To reiterate, the advantage of bootstrapping data before concatenating (or averaging) versus simply concatenating data from multiple sources together, is to ensure that source data are all of exactly the same sample size (so as to not weight more heavily towards the more populous source(s)¹⁴). Bootstrapping also provides a mechanism for propagating all distribution information throughout an aggregation hierarchy and ensures that estimates of variance derived from child distributions are on a consistent scale¹⁵. The latter point is absolutely critical if variance is going to be used to inform a Confidence Rating system and confidence intervals.

Minimum operator procedures are supported by filtering on the lowest performed indicator prior to bootstrapping. Importantly, the bootstrapping routine simply provides a mechanism to collate all sources together to yield a super distribution. Thereafter, the joint distribution can be summarized in what ever manner is deemed appropriate (arithmetic, geometric, harmonic means, medians, variance, range, quantiles etc). Moreover, different levels of the aggregation can be summarized with different statistics if appropriate.

6.1.2 Beta approximation

Whilst the bootstrap aggregation approach described above does offer a robust way to combine data across scales and sources, for large data sets, it does impose large computational and storage burdens. For such cases (large data such as remote sensing), index distributions can be approximated by beta distributions. The beta distribution is defined on the interval [0,1] and is parameterized by two positive shape parameters (α, β) according to the following:

$$f(x; \alpha, \beta) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1} (1 - x)^{\beta-1}$$

A beta function can manifest as many different shapes and as all of these are described by just two shape parameters. Therefore, rather than store all the bootstrapped values for each distribution, we can alternatively approximate each distribution by a beta and store only the defining shape parameters of each distribution. When combining, rather than randomly sample 10,000 stored values of each distribution, we simple resample 10,000 random draws from each beta distribution¹⁶. The combined distribution can then be approximated by a beta distribution and so on.

6.1.3 Weights

Standard bootstrapping yields equally weighted distributions, however, specific weighting schemes can also be easily applied by bootstrapping in proportion to the weights. For example, to weight one parent twice as high as

¹³technically, all equally weighted rather than un-weighted

¹⁴Such weightings should be handled in other ways if at all

¹⁵Variance is inversely proportional to sample size

¹⁶Unfortunately there is no closed-form general formula for the sum of multiple independent beta distributions.

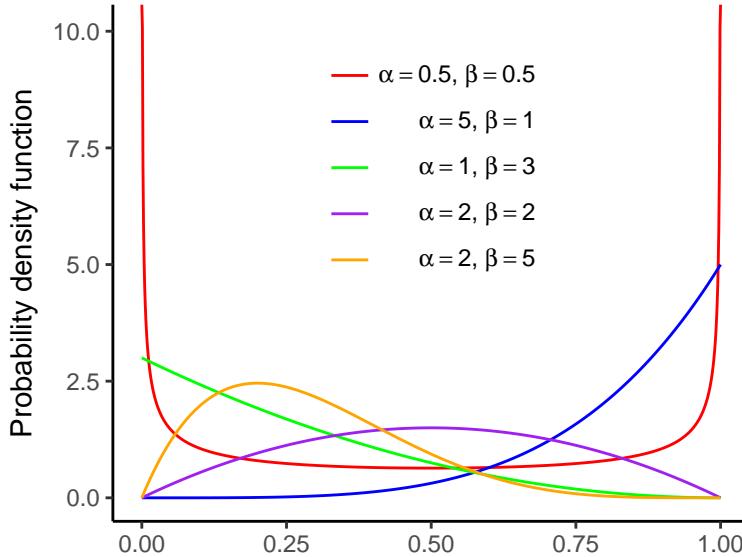

Figure 77: Beta probability densities

another, simply collect twice as many re-samples from the first distribution. To ensure that all resulting distributions have the same size (by default 10,000 items), the number of bootstrap samples collected (n) from each of the (p) parent distributions (i), given the weights (w_i) is calculated as:

$$n_i = (S/p) \times w_i$$

where S is the target size (10,000) and $\lceil \cdot \rceil$ indicates the ceiling. Qualitative data (such as ratings) can also be incorporated by enumerating the categories before bootstrapping.

In addition to allowing expert driven weights that govern the contribution of different items during aggregations, it is possible to weight according to relative spatial areas during spatial aggregations. Currently, all Sites are equally weighted when aggregating to Zone level and all Zones equal when aggregating to Whole of GBR level. That means that small Zones have an equal contribution as large Zones despite representing a smaller fraction of the water body. Area based weights could be applied such that Sites and Zones contribute in proportion to relative areas.

Weights are defined by a user editable configuration file that is similar in structure to the Water Quality thresholds file.

6.1.4 Expert interventions

The ability for experts and Report Card managers to intervene (exclude or overwrite) Scores/Grades at any Spatial/Measure scale is essential to maintain the quality of a Report Card in the event of unrepresentative or suspect data. The current system is able to support expert interventions in the form of exclusions and overwrites. For example, after reviewing the QAQC, an expert can elect to exclude one or more Measures (or Subindicators etc) from one or more spatial scales. Such interventions are specified via a user editable configuration files¹⁷ (csv) that is similar in structure to the Water Quality thresholds file.

The essential component of this configuration file is that it allows a user to specify what Data are to be excluded or replaced. These can be at any of the levels of the Measure hierarchy (Measures, Sub-indications and Indicators) and any level of the Spatial hierarchy (Sites, Zones and Whole GBR). Settings pertaining to levels further along the aggregation hierarchies have precedence. For example, if Chemicals are excluded (or overridden) in a particular Zone, then all Chemical Measures within all Sites will be excluded irrespective of what the settings are for any specific Measure/Site.

¹⁷Since aggregation occurs across two hierarchies (the Measure hierarchy and the Spatial hierarchy - see Figures 74 and 75), two configuration files are necessary.

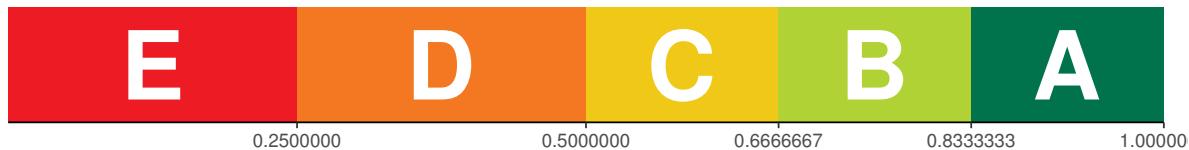

6.1.5 Scores and Grades

The double hierarchy Bootstrap aggregation described above, yields **Score** distributions for each Measure-level/Spatial-level combination. The location and scale of each distribution can thus be described by its mean and variance. Mean **Scores** are then converted into a simple five-point alphanumeric **Grade** scale (and associated colors) using a control chart (see Figure 78).

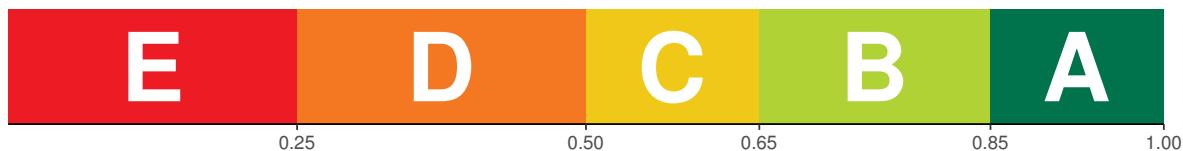

a) Uniform

b) AIMS Marine Monitoring Water Quality and Coral Report Cards

c) Gladstone Healthy Harbour Partnership Environmental Report Card

d) MidCoast Council Waterway and Catchment Report

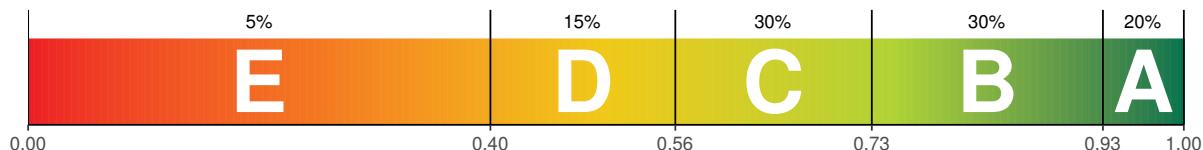

Figure 78: Score to grade conversion control charts. In each case, the scale along the base defines the grade boundaries.

The control charts adopted by the AIMS inshore water quality Marine Monitoring Program (MMP Lønborg et al., 2016) and the Gladstone Healthy Harbour Partnership (Gladstone Healthy Harbour Partnership, 2016) both define two levels (Poor and Very Poor) under the Threshold values and three above (Satisfactory, Good and Very Good). The threshold is purposely placed at the boundary of two grades so as to ease the distinction between 'pass' and 'fail'. The major difference between these two charts is that whereas the AIMS MMP report card control chart partitions the three better than threshold categories, the Gladstone Healthy Harbour Partnership report card control chart employs simpler boundary cutoffs around the 'B' grade (although this does result in arbitrarily unequal category sizes).

By contrast, the MidCoast Council (formally Great Lakes Council) Waterway and Catchment Report (MidCoast Council, 2016) uses grade boundaries based on historical score distribution quantiles associated with definitions of what proportion of total observations (sites) are considered 'Excellent' (A), 'Good' (B), 'Fair' (C), 'Poor' (D) and 'Very Poor' (Fig. 78d). For example, the 'Very Poor' grade was defined as the worst 5% of sites across the entire State of New South Wales and the lowest 5% of sites has a maximum score of 0.4. This approach recognizes the non-linear spread of scores resulting from their particular metrics and attempts to ensure that grades are intuitively interpretable (A grade of A means the site is in Excellent condition). Nevertheless, it does necessitate a of historical data and as well as a very specific and agreed upon set of a priori condition definitions.

In each of the above approaches, grade boundaries are usually determined to some extent by expert panel to ensure that the range of indices represented by each grade classification is congruent with community interpretation of a letter grade report cards. It is far less clear how estimates of uncertainty can be incorporated into such

a grading scheme in a manner that will be intuitive to non-technical audiences. That said, statistical uncertainty is just one of many sources of un- certainty that should be captured into a confidence or certainty rating. Hence any expectations of presenting uncertainty in a quantitative manner may well be unrealistic anyway.

In the absence of expert opinion, we have elected to adopt a very simple score-grade control chart in which the score range is simply partitioned into five equal grades (Fig. 78a).

6.1.6 Certainty rating

Incorporating an estimate of scale (variance) into a certainty or confidence rating necessitates re-scaling the estimates into a standard scale. In particular, whereas a scale parameter of high magnitude indicates lower degrees of certainty, for a certainty rating to be useful for end users, larger numbers should probably represent higher degrees of certainty. Thus, the scaling process should also reverse the scale. Furthermore, variance is dependent on the magnitude of the values.

In order to re-scale a scale estimate into a certainty rating, it is necessary to establish the range of values possible for the scale estimate. Whilst the minimum is simple enough (it will typically be 0), determining the maximum is a little more challenging depending on the aggregation algorithm (bootstrapping, Bayesian Network etc). One of the advantages in utilizing proportional distributions (such as is the case for a Bayesian Network or a re-sampled bootstrap distribution) is that the scale parameter for the single worst case scenario can be devised (once the worst case scenario has been determined) independent of sample sizes or weightings. In most situations this is going to be when the distribution comprises equal mass at (and only at) each of the two extremes (for example, values of just 0 and 1).

The measure of confidence rating discussed above is purely an objective metric derived from the variance in the aggregation hierarchy. It is completely naive to issues such as missing data, outliers and Limit of Detection issues - the influences of which on a confidence rating are necessarily subjective. A full Confidence Rating would combine these objective variance component with additional subjective considerations such as climatic and disturbance information, and the perceived influence of missing, Limit of Detection and outlying data. Hence, the statistical scaled statistical variance would form just one component in the Confidence Rating system.

The bootstrap aggregation method provides a mechanism for estimating variance from which to build such an expert considered Confidence Rating system.

Table 16 presents the Water Quality Indicator Scores and associated Grades for each Zone based on three of the grade control chart types described in Figure 78 for the eReefs data indexed using the fsMAMP formulation. Whilst there is some agreement between the different grade types, in general, the Uniform type yields higher grades than either MMP or GHHP.

Table 16: Score and associated Grades based on three different grade control charts (Uniform, MMP and GHHP) for eReefs data indexed via fsMAMP and aggregated to Zone/Indicator level.

6.1.7 Confidence intervals

Confidence intervals (CI) represent the intervals in which we have a certain degree of confidence (e.g. 95%) that repeated estimates will fall. Hence the 95% CI of the mean is the range defined by the quantiles representing 95% of repeated estimates of the mean.

To calculate 95% confidence intervals for bootstrap aggregated distributions (e.g. Site I/Chemical distribution), we repeatedly¹⁸ draw a single sample from each of the constituent distributions (e.g. a single value from the Site I Ammonia, Chlorophyll-a and NOx distributions) and from each set of draws, calculate the weighted¹⁹ mean of the values. The 95% CI is thus calculated as the quantiles ($p=0.025$ and $p=0.975$) of the means.

Confidence intervals are used to represent uncertainty in estimations. For example, 95% confidence intervals associated with a estimated mean roughly express a range of values over which we have the nominated degree of confidence that the true value is likely to lie²⁰.

Uncertainty arrises from multiple sources. Firstly, it arrises from the accuracies of the measured data and secondly, from the imprecisions introduced by the statistical methodologies for processing and summarizing the dat. Hence encapsulating and communicating full uncertainty requires information about both of these sources of uncertainty.

Estimates (such as sample means) are typically calculated from very small (yet ideally representative) samples drawn from a much larger population. In such cases, the statistically derived confidence intervals are used to provide an indication of the range of estimates in which we are confident the true value is likely to lie. That is, they depict the statistical uncertainty that arrizes from the need to estimate parameters from small amounts of the total possible spatial/temporal domain.

If measurement uncertainty is also known, then it is possible to incorporate and propogate this through the aggregation schedule so as to yeild total uncertainty. Measurement uncertainty is very typically very difficult to obtain. Nevertheless, it is usually assumed to be relatively small compared to the statistical uncertainty.

However, in the case of the Satellite and eReefs data, we have a virtual saturation of sample data. That is, with respect to the spatial and temporal extent of the data, we essentially have the entire population. Consequently, the statistical uncertainty is virtually zero. We are not estimating a mean, we are calculating the mean. Hence

¹⁸The more repeated draws the closer the distribution of means will converge. For the current project, the number of repeated draws is 10,000.

¹⁹Weights according to the weights defined for that level of the aggregation hierarchy

²⁰From a frequentist perspective, 95% confidence intervals technically indicate that 95% of intervals of the calculated extent will contain the true mean

measurement uncertainty is of elevated importance. Unfortunately, we do not have any information about the measurement uncertainty at a spatial and temporal scale appropriate. As a result, we have elected not to represent uncertainty (as it would only be based on statistical uncertainty which would give the misleading impression of extremely low levels of uncertainty).

6.2 Summary of adopted methodologies

The aggregation schedule can be summarized as:

A. Calculation of Zone level Score and Grades

1. Collect raw data (= **Measures**) at each fixed monitoring site and compare individual observations to associated threshold/benchmark/reference or set of expectation ranges
2. Create indexed data as an expression of degree of difference (*scaled modified amplitude method*) to yield a **Score** for each **Measure** per sampling location (e.g. Site) (applies to Measures in all Indicators, Water Quality). In the absence of thresholds (e.g. Measures within Plankton), observed data are rescaled to a range defined by historical quantiles (20th and 80th percentiles) for each Measure.
3. Apply any expert opinion interventions
4. Combine **Measure** Scores into **Site-level Sub-indicator** Scores by averaging taking into account any weightings, i.e. aggregate into observation-level Sub-indicator Scores. This step involves **Bootstrapping** each input to distributions of 10,000 re-samples (or fewer if weighted), combining distributions and finally Bootstrapping again into a single 10,000 size distribution.
5. Combine **Sub-indicator** Scores into **Site-level Indicator** Scores by averaging, i.e. aggregate into Site-level Indicator Scores.
6. Convert Scores into coloured **Grades** (A-E) for visual presentation in report card

B. Calculation of Zone level Grades

1. Aggregate **Site-level Indicator** Scores from step A.5 into **Zone-level Indicator** Scores by averaging (incorporating spatial weights)
2. Aggregate **Zone-level Indicator** Scores into **Zone-level Component** Scores by averaging (incorporating weights)

C. Calculation of Whole GBR Grades

1. Aggregate **Zone-level Indicator** Scores from step B.1 into **Whole GBR-level Indicator** Scores by averaging (incorporating spatial weights)
2. Aggregate **Whole GBR-level Indicator** Scores into **Whole GBR-level Component** Scores by averaging (incorporating weights)

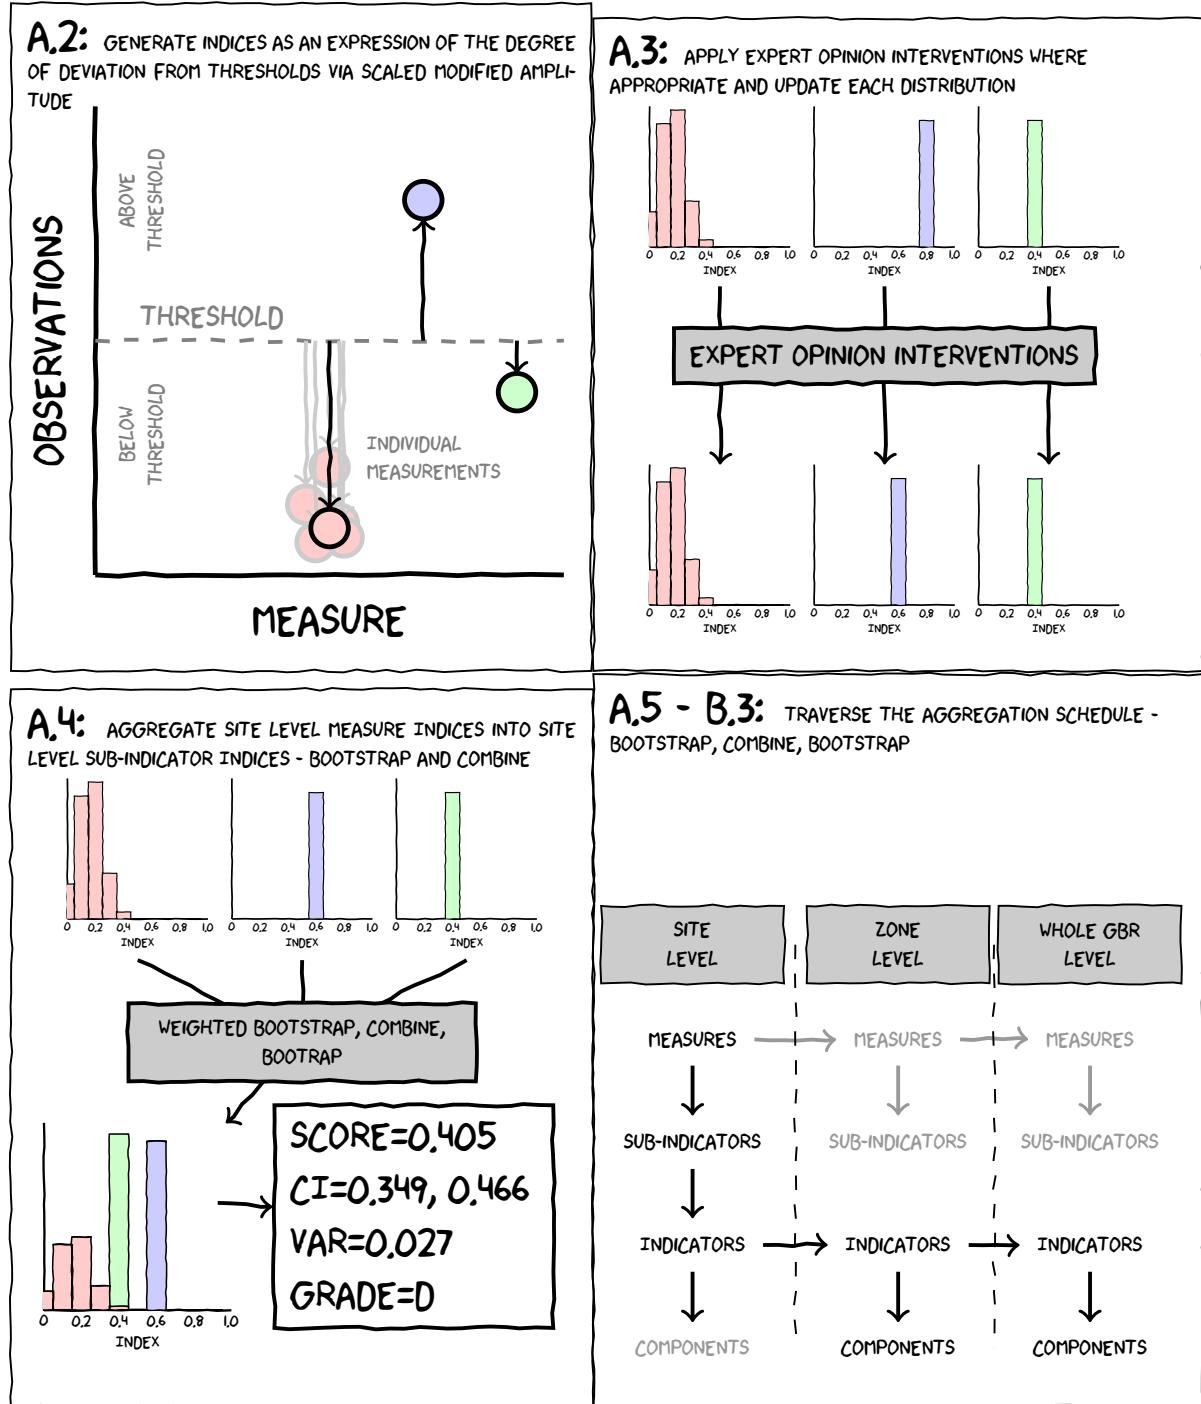

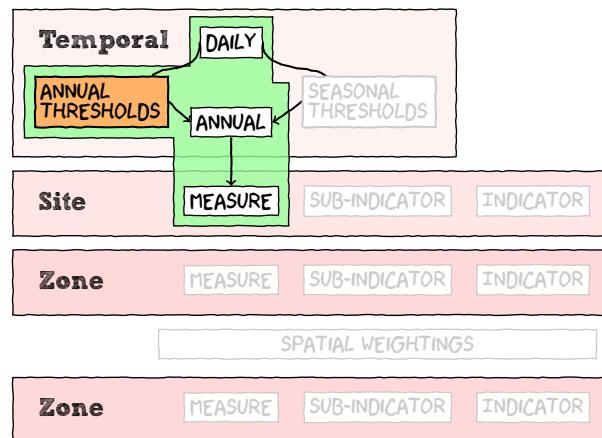

Figure 79: Schematic illustrating the major steps of the GBR Report Card. In this fabricated example, there are three Measures (Red, Green and Blue). Each of the Blue and Green Measures are represented by a single discrete observation, whereas the Red Measure is represented by a large collection of observations. Expert option intervened to lower the blue Measure distribution from observed values at 0.8 to 0.6.

6.3 Aggregation summaries

The ISP have indicated that the Water Quality metric should be based purely on eReefs fsMAMP indexed Chlorophyll-a and Secchi Depth and that the conversion of scores to grades should follow a uniform control chart. Consequently, this section will only present graphical summaries for these metric determinants. Other aggregation combinations can be found in Appendix ??.

6.6 Summary of recommendations

7. EXPLORATION OF FOCAL AREAS

In addition to working with the 24 large GBRMPA regions and water bodies, it is possible to define very specific spatial and temporal domains that might represent areas of greater focus. For example, it might be of interest to model water quality patterns in a defined area proximal to a source of river discharge as part of an exploration into water quality responses to catchment outcomes.

Small spatial domains also presents an opportunity to explore data assimilation options. The current project has access to four streams of water quality data (discrete AIMS niskin samples, AIMS FLNTU data, Satellite remote sensing and eReefs modelled data). Assimilating eReefs data (4km resolution) and Satellite data (1km resolution) as presented in the eReefs model data represents substantial computational overheads as a result of their high dimensionality. Whilst the discrete AIMS niskin sample is substantially more sparse, it does nonetheless present its own challenges when it comes to assimilation (see below).

We have three choices for combining the discrete AIMS niskin sample data with the eReefs assimilated model data:

1. aggregate together the average discrete (Niskin) sample and the average eReefs data or indices.
2. assimilate via an Ensemble Kalman Filter similar to the eReefs/Satellite data assimilation
3. define a Gaussian Process that incorporates both the discrete AIMS niskin data and eReefs assimilated data
4. assimilate via Fixed Rank Kriging

As a motivating example, we will use the discrete AIMS niskin and eReefs model data surrounding a single Dry Tropics Midshelf AIMS MMP site (Yongala). Yongala is a deep water site and thus the eReefs and discrete AIMS niskin samples are likely to have been collected across a relatively homogeneous bathymetry. Initial discussions will focus only on data from a single day (25/03/2017). The spatial configuration of eReefs observations relative to the AIMS MMP Yongala niskin sampling location is displayed in Figure 108.

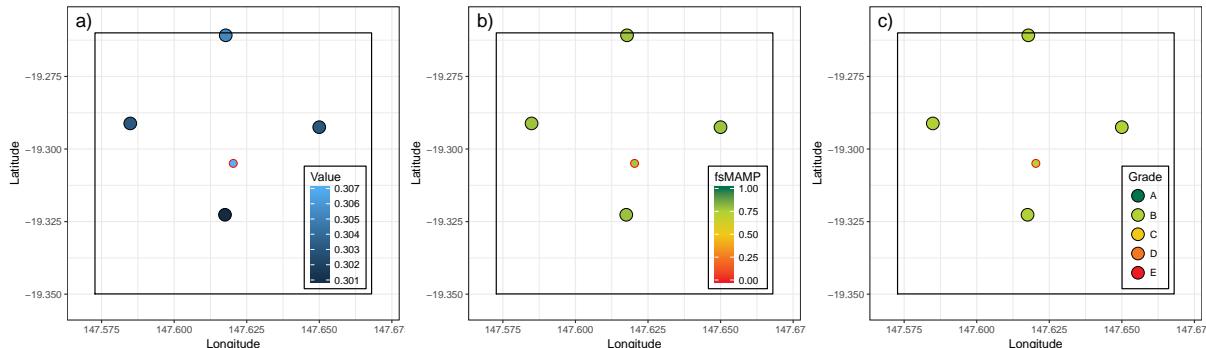

Figure 108: Spatial distribution of eReefs observation locations within 5km of the Yongala AIMS MMP niskin sampling location (point with red outline). Observations represent a) Chlorophyll-a values and associated b) fsMAMP indices and c) Grades (Uniform control chart) for 25/03/2015.

Importantly, although the AIMS niskin sample is located geographically roughly in the middle of the eReef locations, its Chlorophyll-a value (and fsMAMP index) is higher (and lower) than the surrounding eReefs values. Although this is only subtle in this example, it will be drawn upon when discussing aggregation options.

The fact that the observed AIMS niskin Chlorophyll-a sample collected on 25/03/2015 is higher than the surrounding eReefs estimates might suggest that either or both observation sets are only representative of limited scales. More specifically, it is likely that whilst the AIMS niskin samples only accurately reflect very local conditions, the 4km eReefs data are only likely to be reflective of broad larger scale conditions²¹.

The above situation is likely to be exacerbated in highly heterogeneous seascapes. AIMS niskin samples are typically collected in close proximity to coral reefs where the general hydrology and input process might be

²¹The eReefs observations represent average modelled conditions within a 4x4km square cell, and therefore whilst potentially broadly reflective of large scale conditions, may not actually be an accurate reflection of anywhere in that 4x4km cell

substantially different to the surrounding deeper water. By contrast, the eReefs model is known to be less reliable in shallow water. Thus, in areas that are heterogeneous with respect to bathymetry and hydrology, the AIMS niskin observations are likely to be representative of only the immediate vicinity (with very similar hydrology etc), whereas the eReefs observations might represent 'average' conditions that are only appropriate when considered on relatively large scales. The 4km resolution of eReefs model is unlikely to present adequate granularity in areas that are heterogeneous with respect to bathymetry and hydrology.

Hence, the scale incompatibilities are likely to limit the ability to combine these two sources of data in a meaningful and reliable manner.

It is also possible that the accuracy of the two sources differ. Unfortunately, in the absence of a 'truth' this is difficult to assess. Nevertheless, since the eReefs data are indirect measures, it is possible that they are not as accurate as the AIMS niskin observations. If we had co-located observations (observations collected at the same locations and times from each source), we could attempt to align or calibrate the sources to one another. However, it is not possible to perform such alignments when data are not co-located and there is suspected differences in their spatial representation envelopes.

7.1 Simple aggregation

If we initially ignore all temporal aspects of the data and focus on the single day (25/03/2015), we could aggregate together the single discrete AIMS Niskin sample observation with the average of the four eReefs observations to yield a single Chlorophyll-a estimate for the Yongala focal area (see Figure 109a). Alternatively, we could aggregate Chlorophyll-a indices (see Figure 109b-c).

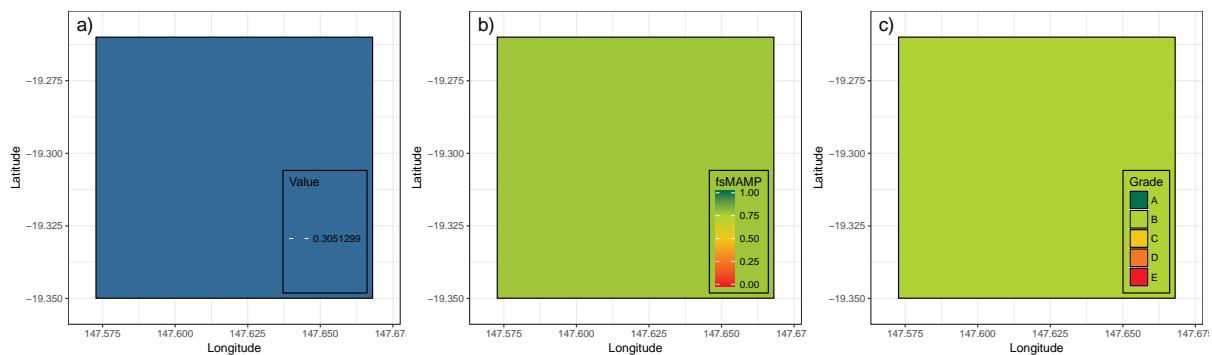

Figure 109: Yongala focal area aggregated a) Chlorophyll-a values and associated b) fsMAMP indices and c) Grades (Uniform control chart) for 25/03/2015.

Critically, this technique does assume that the single discrete AIMS niskin sample is representative of the entire spatial domain of the Yongala focal area. That is, we assume that the focal area mean is equal to this single point estimate. As previously discussed, this is likely to be an unrealistic expectation. We currently do not have any information on the spatial envelope represented by discrete samples. It is highly likely that the discrete samples are spatially biased (unrepresentative of the broader area as they are typically designed to sample reefs rather than the general water body). Rather it is likely that the discrete sample only represent the immediate vicinity and uncertainty should decline with increasing distance. That said, the form to which certainty (representation) declines is completely unknown making it impossible to incorporate.

Furthermore, for the purpose of propagating uncertainty, the spatial uncertainty associated with the AIMS niskin sample is assumed to remain constant throughout this focal area. That is, our confidence in the focal mean is informed purely in our confidence in the single observation and that there is no additional loss of confidence associated with increasing distance from the sampling location. Obviously, it is highly unlikely that the reliability of the estimate will remain constant. The same is true for eReefs data, although it is likely to be less of an issue due to the greater sample size and spatial extent.

7.2 Ensemble Kalman Filter data assimilation

This is the approach used to assimilate the Satellite data into the eReefs model. Data Assimilation (DA) is a technique with forecasting and reanalysis, the latter of which involves conditioning estimates of state on multiple

sources of data. For example, high density modelled data based on thermodynamics and gas laws might be 'calibrated' or orgmented by data observed at weather stations. The Kalman filter estimates state as the joint probability distribution ($p(x|y)$) which according to Bayes rule is proportional to the prior probaility ($p(x)$) multiplied by the probability (likelihood) of the observational data ($p(y|x)$). The simple Kalman filter provides algebraic expressions that describe the transition of state mean and covariance over time assuming all probability density functions are Gaussian and the transition is linear. If we say we have a prior belief that the state (x) has a mean of μ and covariance of Q and that the data (d) have an expected value of Hx and covariance of R , it can be shown that the posterior mean ($\hat{\mu}$) and covariance (\hat{Q}) are:

$$\hat{\mu} = \mu + K(d - Hx), \hat{Q} = (I - KH)Q$$

where K (the Kalman gain) is:

$$K = QH^T(HQH^T + R)^{-1}$$

Unfortunately, as the domain of x increases (higher dimensionality), the covariance becomes prohibitively large. If however, the state space (x) is broken up into a series of states (each perhaps representing a small subset (or ensemble) over time/space), we can replace Q with C (the sample covariance).

In either case, we must have estimates of both C and R . Whilst we can obtain estimates of C , estimates of R are not possible. If we only have a single discrete value within a higher-dimensional model domain, then we have no way of estimating R . Furthermore, even in larger focal areas that might contain multiple discrete samples, the samples are too spread out both spatially and temporally to be able to estimate R with any accuracy or reliability. For example, whilst the samples are typically separated in space by 10's of kilometers and months in time, water samples are likely to vary over the scale of meters and hours.

7.3 Gaussian Processes

A Gaussian distribution represents the distribution of observations that are themselves the result of an infinite number of influences (or processes). They are widely used to represent the distribution of residuals (unexplained component) when modelling data as it is often assumed that the unexplained component is due to a huge number of additional, unmeasured influences. In traditional linear modelling, we assume that not only are the residuals normally (Gaussian) distributed, we also assume that they are independent (not spatially or temporally correlated) and equally varied around 0.

$$\varepsilon_i \sim \mathcal{N}(0, \Sigma) \quad \Sigma = \begin{pmatrix} \sigma^2 & 0 & \dots & 0 \\ 0 & \sigma^2 & \dots & \vdots \\ \vdots & \dots & \sigma^2 & \vdots \\ 0 & \dots & \dots & \sigma^2 \end{pmatrix}$$

Similarly, rather than express the stochastic elements as a vector of residuals drawn from a normal distribution, we can model the observed data as a multivariate normal (Gaussian) distribution. In this case, we are assuming that each of the observations is drawn from a multivariate normal distribution with different means and covariances).

This same argument could be extended to describe the distribution from which functions are drawn. Observed data are the result of the sum of an in infinite number of processes (including measurement error). Many of these processes vary over space and time such that sampling units that are closer together in space and time tend to be more similar to one another than they are to more distant units.

$$y_i \sim \mathcal{MVN}(M, C)$$

A Gaussian Process is largely defined by the covariance matrix ($k(x, x')$). Actually k is referred to as the **kernel**. We can define any covariance (kernel) function provided it is semi-definite - essentially that it is a symmetrical matrix.

A few of the popular kernels are described in the following Table 17.

Table 17: Simple Gaussian Process kernel functions

Kernel	Function
Linear	$k(x, x') = \sigma_f^2 xx'$
Squared exponential	$k(x, x') = \sigma_f^2 \exp\left[\frac{-(x-x')^2}{l^2}\right]$
Periodic	$k(x, x') = \sigma_f^2 \exp\left[\frac{-2 \sin^2(\pi(x-x')/p)}{l^2}\right]$
Periodic exponential	$k(x, x') = \sigma_f^2 \exp\left[\frac{-2 \sin^2(\pi(x-x')/p)}{l_1^2}\right] \exp\left[\frac{-(x-x')^2}{l_2^2}\right]$
Matern	$k(x, x') = \sigma_f^2 \frac{1}{\Gamma(v) 2^{v-1}} \left[\frac{\sqrt{2v} (x-x') }{l} \right]^v K_v \left[\frac{\sqrt{2v} (x-x') }{l} \right]$

In Table 17, x and x' are vectors of the X variable. x' just indicates a transposed version of the vector. Hence $(x - x')$ indicates the difference (distance) between each pair of x values (they are squared so that they are all positive). When two points are similar, $k(x, x')$ approaches 1 (perfect correlation). Smoothing is based on neighbours exerting influence on one another (being correlated). When two points are very distant $k(x, x')$ approaches 0. The l are length scale parameters that determines the degree of contagion - that is, they determine the rate that the influence of points deteriorates with distance.

Assuming that the covariance pattern defined by the GP parameters (e.g. σ_f^2 and l) and observation space reliably reflects the underlying processes, the same parameters can be applied to yield a covariance structures for predicting mean and variance across a noval (yet overlapping) space. Specifically, if the covariance across the observed space is K_{oo} , the covariance between observed and prediction space is K_{op} and the covariance across prediction space is K_{pp} , then the mean and variance for predicted values are:

$$\bar{y}_p = K_{op}(K_{oo} + \sigma_o^2 I)^{-1} K_{op}^T y_o$$

and

$$var(y_p) = K_{pp} - K_{op}(K_{oo} + \sigma_o^2 I)^{-1} K_{op}^T$$

where σ_o^2 is the estimated variance (uncertainty) in the observations, I is an identity matrix of equivalent dimensionality to K_{oo} and K_{op}^T is the transpose of K_{op} .

Gaussian Processes could be used to fit smooth multidimensional smoothers separate over each source so as to estimate parameters and uncertainty at any granularity. Whilst this might be appropriate for the eReefs data, it is not possible to build a reasonable gaussian process via a single point without external estimates of the covariance over functions (σ_f^2) and the length (wigginess) of the smoother.

Normally a Gaussian Process is applied to a single source for the purpose of kriging (smoothing). Nevertheless, it could be argued that there are a single set of underlying processes driving spatio-temporal patterns of water quality (e.g. l and σ_f^2) and that the multiple sources (AIMS niskin and eReefs) represent alternative ways to sample observations from those processes. Ideally, any differences between the sources should purely be differences in accuracy and uncertainty. If this is the case, rather than assume all observations are associated with the same σ_o^2 , we could associate one variance to the AIMS niskin observations (σ_n^2) and another to the eReefs observations (σ_e^2).

Figure 110 illustrates a squared exponential Gaussian Processes with different parameter values applied to a single dimension (Latitude) of the 25/03/2015 Yongala focal area data. In each case, the variability (uncertainty) of the AIMS niskin observations was defined as 10 times lower than that of the eReefs observations. Values of σ_f^2 and l were chosen to represent specific sets of scenarios. For example, lower σ_f^2 imposes a lower maximum covariance

and a lower l dictates a more rapid decline in the autocorrelation over distance. Whilst it is possible to apply these functions in an optimizing framework so as to allow the data to determine the most appropriate values for σ_f^2 and l , σ_n^2 and σ_e^2 must be supplied based on external estimates.

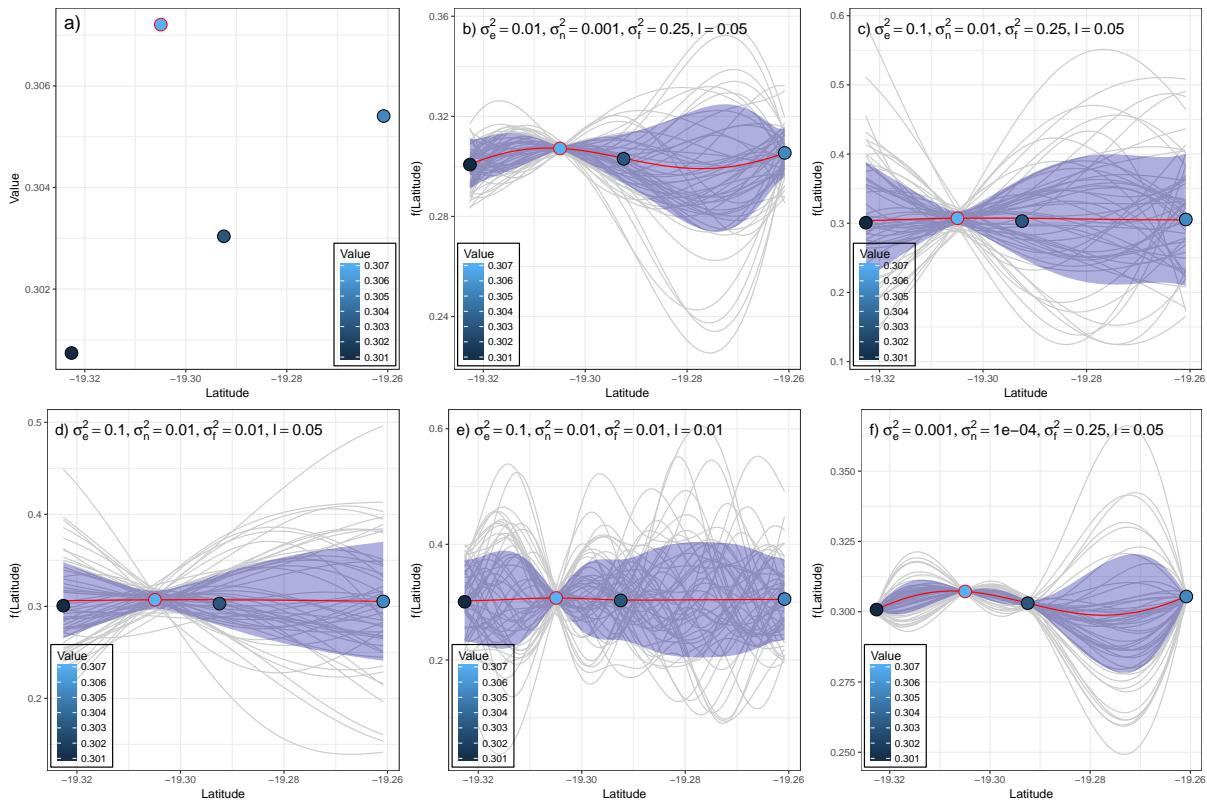

Figure 110: Illustration of data assimilation via squared exponential Gaussian process applied to a single dimension (Latitude) for the 25/03/2015 Yongala focal area a) Raw Chlorophyll-a values and b-e) different Gaussian Process parameters.

Similar to the Kalman Filter, high dimensionality incurs substantial covariance size increases. Every one additional observation results in a doubling of the covariance matrix and a tripling of memory to invert this the covariance matrix. Hence, practical applications employ either ensemble-like approaches or more commonly, sparse covariance matrices²² to reduce the imposition of dimensionality.

Addition of a temporal dimension substantially increases the complexity of the problem. Not only does the covariance structures have to account for variability and autocorrelation length over space, it also has to reflect patterns of variability over time. Importantly, it is not just how isolated spatial points change over time. Temporal autocorrelation also occurs between neighbouring points.

7.4 Fixed Rank Kriging

Fixed Rank Gridding (FRK) is a spatio-temporal modelling and prediction framework in which spatially/temporally correlated random processes are decomposed via linear combinations of basis functions (Φ) along with associated fine-scale variation (ν) (Cressie and Johannesson, 2008).

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \Phi\boldsymbol{\alpha} + \boldsymbol{\nu}$$

The use of relatively small numbers of basis functions permits substantial dimensionality reductions that offers a scalable solution for very large data sets. Moreover, the framework facilitates differing spatial support hence allowing some capacity for the 'fusion' of multiple sources with different footprints.

²²Sparse matrices acknowledge that covariance will decline over time and distance and at some distance, the covariance will effectively be zero.

Varying footprints are accommodated by arranging the point-referenced data into grids, the granularity of which is proportional to the footprint or extent of support. For example, the AIMS niskin data and eReefs modelled data could be discretized into a small and set of larger grid squares (see Figure 111b - pale red and blue squares respectively). Whilst the footprint size for the eReefs modelled data was based on the cell grid onto which the model is projected, the AIMS niskin footprint was set to an arbitrarily (smaller) value to illustrate varying degrees of support.

The full spatio-temporal domain is also discretized into a regular grid of smaller cells called *basic areal units* (BAU) which represent the smallest modelling and prediction unit. In this example, we have discretized the spatial domain by hexagonal cells 0.01 degrees longitude by 0.01 degrees latitude (see Figure 111b - black hexagons). Within the model, varying support is then based on the intersection of the square footprints with the BAUs.

For this example, we have elected to define two regularly spaced basis functions based on Matern covariance (smoothing parameter of 1.5) to be used in the decomposition of spatio-temporal processes (see Figure 111c). The multiple resolutions provide a mechanism for estimating the scale of spatio-temporal autocorrelation (however, ideally this requires a substantially larger grid of data than our example).

The basis function covariance matrices and fine-scale variance parameters are estimated via a expectation maximization (EM) algorithm and thereafter used to project predictions onto the scale of the BAU's (see Figure 111d). These predicted values have also been indexed via fsMAMP (see Figure 111e) and converted into Grades (see Figure 111f).

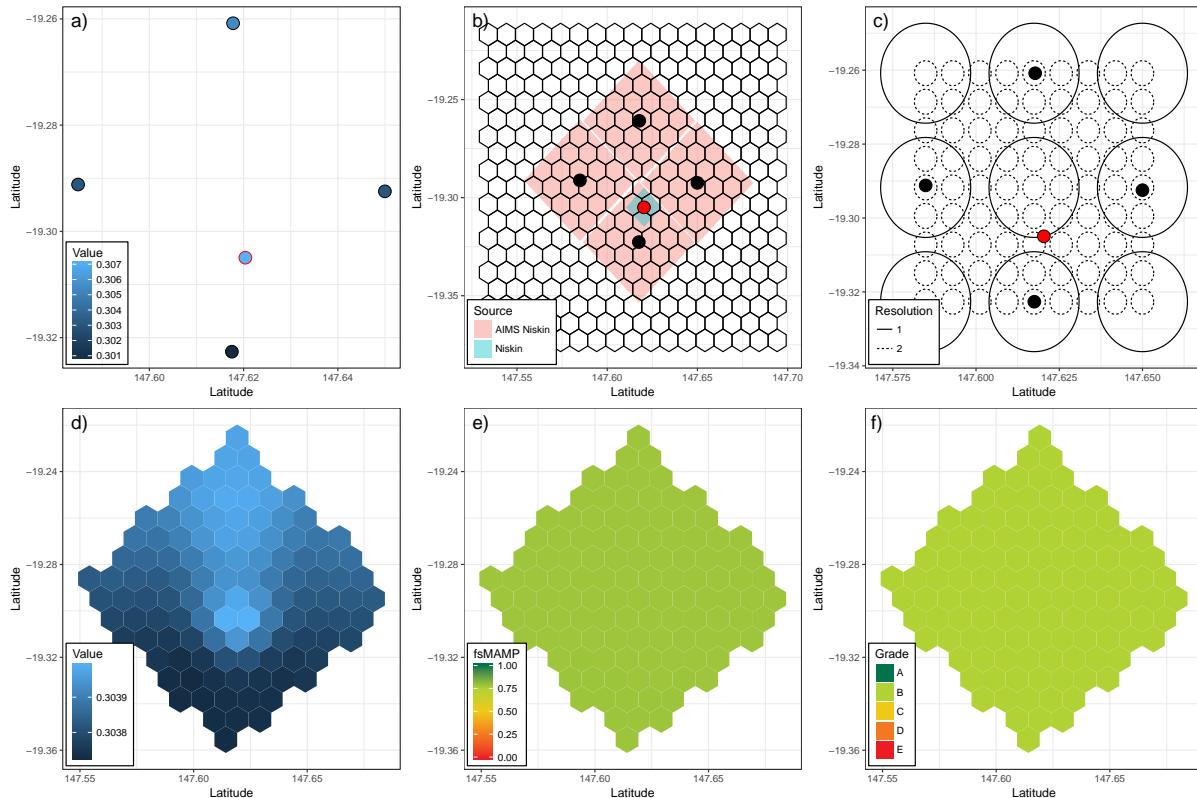

Figure 111: Illustration of data assimilation via Fixed Rank Kriging applied to spatial data for the 25/03/2015 Yongala focal area a) Raw Chlorophyll-a values (AIMS niskin: red symbol border, eReefs: black symbol border), b) discretization of the spatial domain into a regular hexagonal grid and varying footprints (support) for AIMS niskin (blue) and eReefs (red), d) Matern basis functions of two resolutions, d) predicted values and associated e) fsMAMP indices and f) Grades (Uniform control chart) for 25/03/2015.

Figure 111 illustrates that whilst fixed rank kriging does offer an option for the assimilation (or fusion) of multiple data sets, in the absence of measurement error, it does assume that all observations are equally accurate. Figure 111d shows a bright spot associated with the higher AIMS niskin Chlorophyll-a value. It is important to reiterate that the extent of this bright spot is due to both the higher Chlorophyll-a observation of the AIMS niskin sample and the arbitrary size of the footprint. To be a meaningful fusion, reasonable estimates of the spatio-temporal

extent of representation of the AIMS niskin data will need to be obtained along with estimates of measurement error in both the AIMS niskin and eReefs modelled data.

Spatio-temporal basis functions can be constructed as the tensor product of spatial basis functions and similarly defined temporal basis functions. Measurement error (if known) can also be incorporated.

More recently, Nguyen et al. (2014) has proposed a data assimilation technique for big data that is essentially a blend of fixed rank kriging and Kalman filtering and looks to have some promise.

8. ACKNOWLEDGEMENTS

The model simulations were developed as part of the eReefs project, a public-private collaboration between Australia's leading operational and scientific research agencies, government, and corporate Australia. Atmospherically-corrected MODIS products were sourced from the Integrated Marine Observing System (IMOS) - IMOS is supported by the Australian Government through the National Collaborative Research Infrastructure Strategy and the Super Science Initiative."

Appendices

A. THRESHOLDS

Table A1: Water Quality Threshold values for each Measure in each Zone (Region/Water Body). Thresholds values are similar to annual Guideline values. Wet and Dry represent Wet and Dry season thresholds respectively. Direction of Failure indicates whether a values higher ("H") or lower ("L") than a Threshold would constitute an exceedence. Range From and Range To represent Thresholds for Measures that have a range of optimum values (such as dissolved oxygen or pH).

Measure	Units	Water Body	Region	Threshold		Direction of Failure	Justification
				Annual	Dry		
chl	$\mu\text{g L}^{-1}$	Enclosed Coastal	Cape York	2.00	2.00	H	QLD WQ guidelines
chl	$\mu\text{g L}^{-1}$	Enclosed Coastal	Wet Tropics	1.10	1.10	H	There is no seasonal adjustment
chl	$\mu\text{g L}^{-1}$	Enclosed Coastal	Dry Tropics	1.00	1.00	H

B. EREEFS MODELS

Table B2: eReefs regional biogeochemical simulation catalog.

Simulation name	Projects	Date range	Delivery	Notes/Improvements
GBR4_H1p85_B1p0_Cbas_Dhind	SIEF	Jan 1, 2011 – Jun 30, 2014	Available on NCI	Simulation delivered as part of SIEF project (previously known as 926). Skill assessment available in SIEF report.

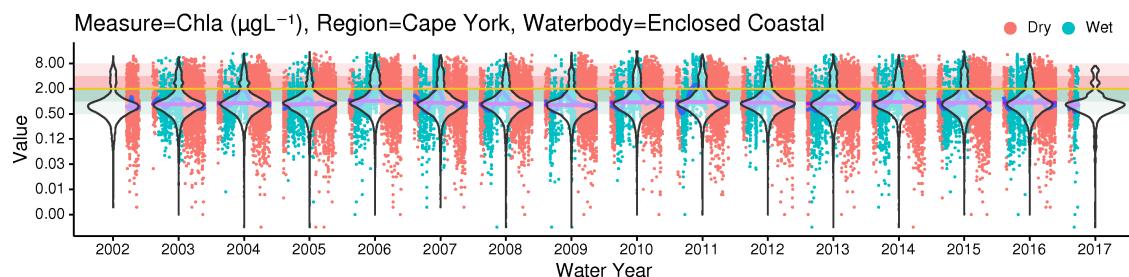

C. EXPLORATORY DATA ANALYSIS

C.I Annual data

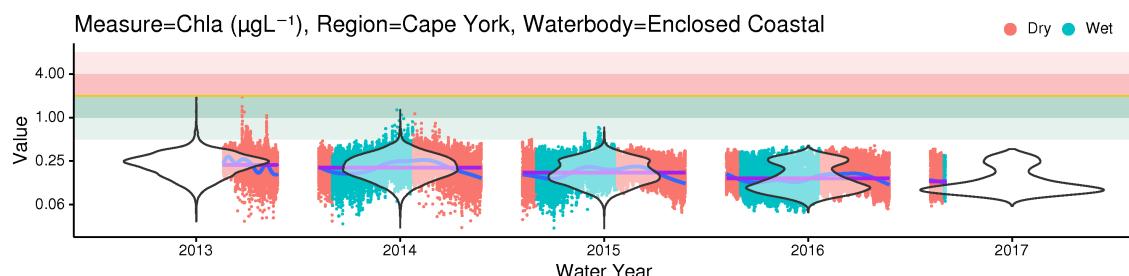

C.I.1 Cape York, Enclosed Coastal

C.I.1.1 Chlorophyll

c) Satellite

d) eReefs

e) eReefs926

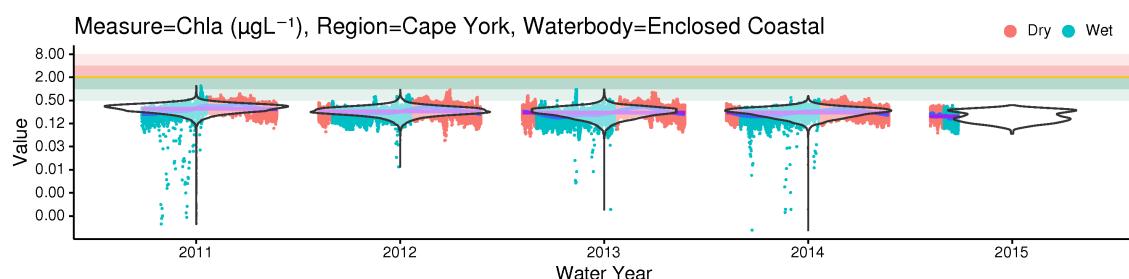

Figure C1: Observed (logarithmic axis with violin plot overlay) Chlorophyll-a data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

C.I.1.2 Total Suspended Solids

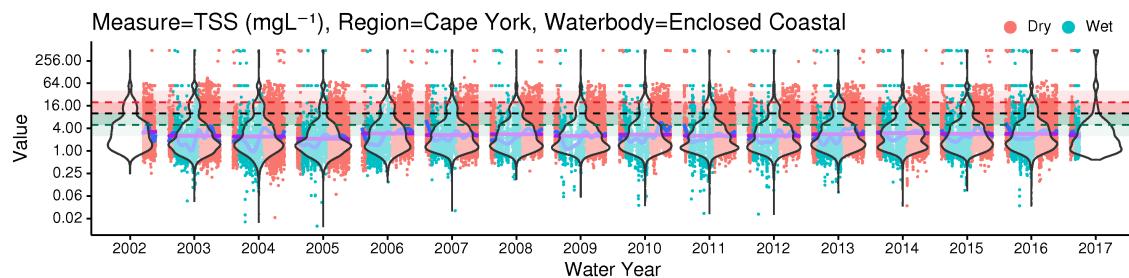

C.I.1.3 Secchi Depth

C.I.1.4 NOx

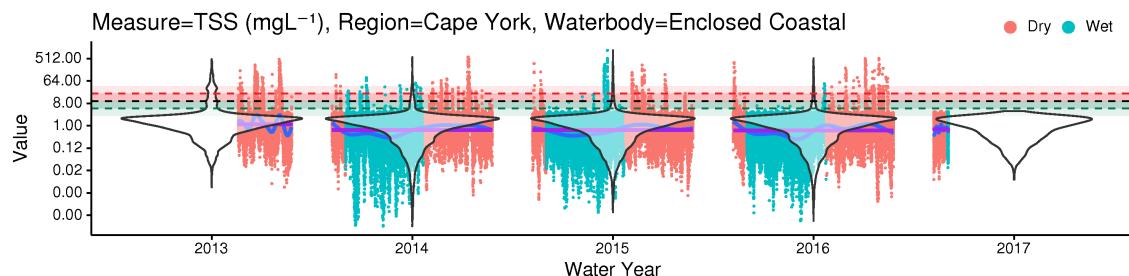

C.I.2 Cape York, Open Coastal

C.I.2.1 Chlorophyll

c) Satellite

d) eReefs

e) eReefs926

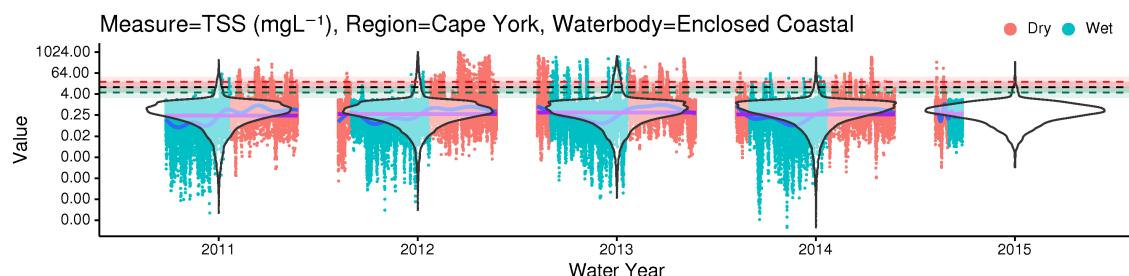

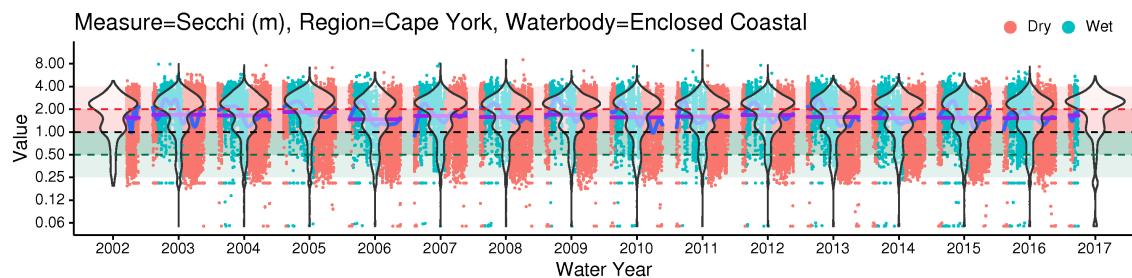

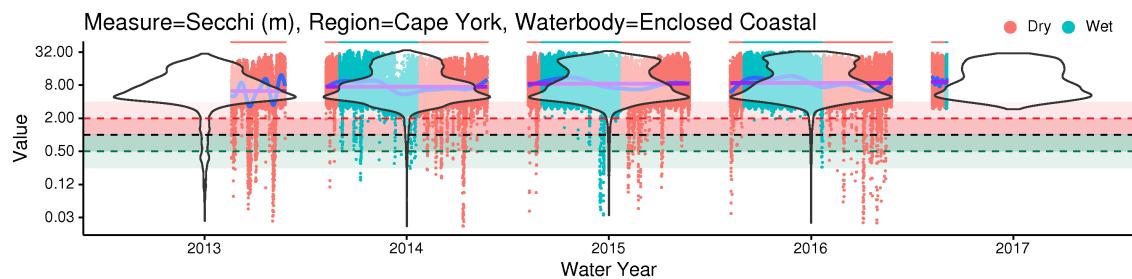

Figure C2: Observed (logarithmic axis with violin plot overlay) Total Suspended Solids data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

c) Satellite

d) eReefs

e) eReefs926

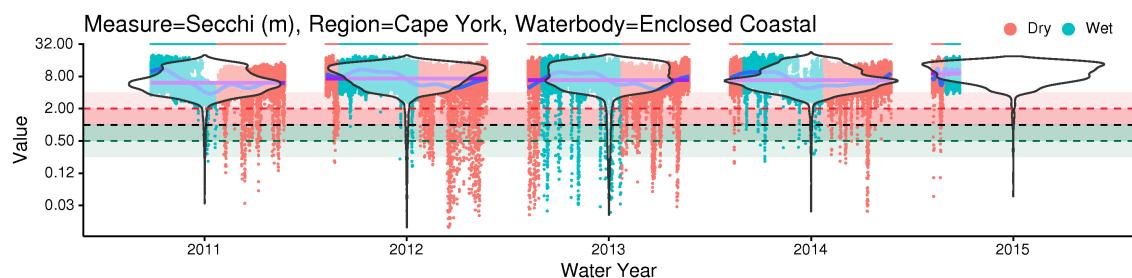

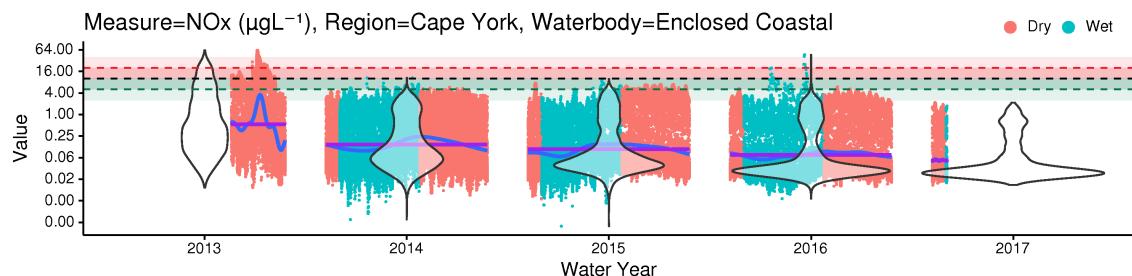

Figure C3: Observed (logarithmic axis with violin plot overlay) Secchi Depth data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

c) Satellite

d) eReefs

e) eReefs926

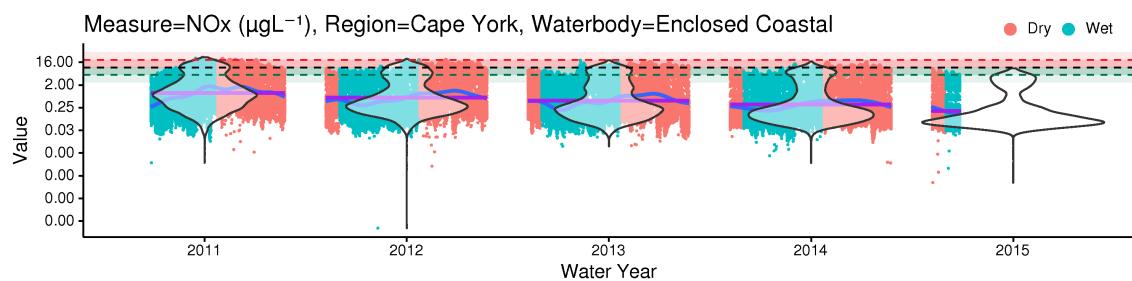

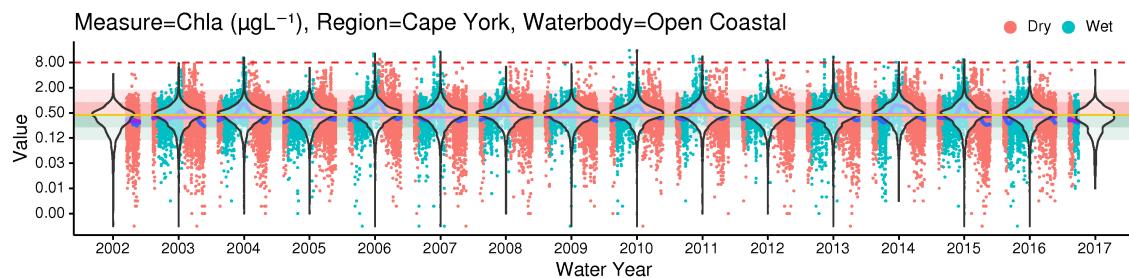

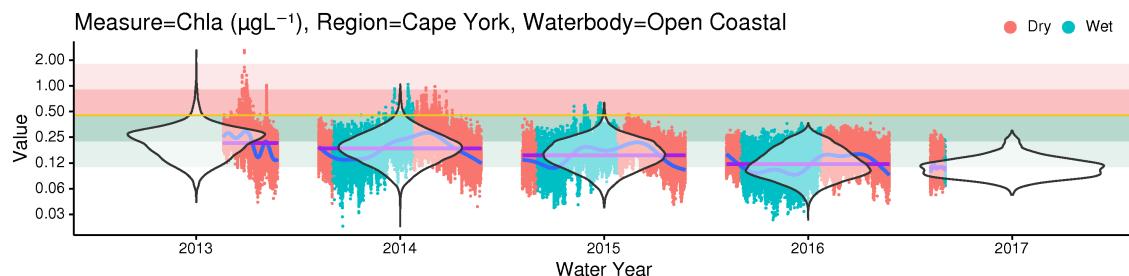

Figure C4: Observed (logarithmic axis with violin plot overlay) NOx data for the Cape York Enclosed Coastal Zone from a) AIMS insitu, b) AIMS FLNTU, c) Satellite, d) eReefs and e) eReefs926. Observations are ordered over time and colored conditional on season as Wet (blue symbols) and Dry (red symbols). Blue smoother represents Generalized Additive Mixed Model within a water year and purple line represents average within the water year. Horizontal red, black and green dashed lines denote the twice threshold, threshold and half threshold values respectively. Red and green background shading indicates the range (10% shade: $x4/4$; 30% shade: $x2/2$) above and below threshold respectively.

Red and Blue symbols represent samples collected in Dry and Wet seasons respectively. Green and red shaded banding on a) respectively represent half and twice threshold value (50% shading) and one-fourth and four times threshold value (30% shading). Traffic-light banding on b-d) indicates simple 5-level color scheme. Purple lines represent annual means.

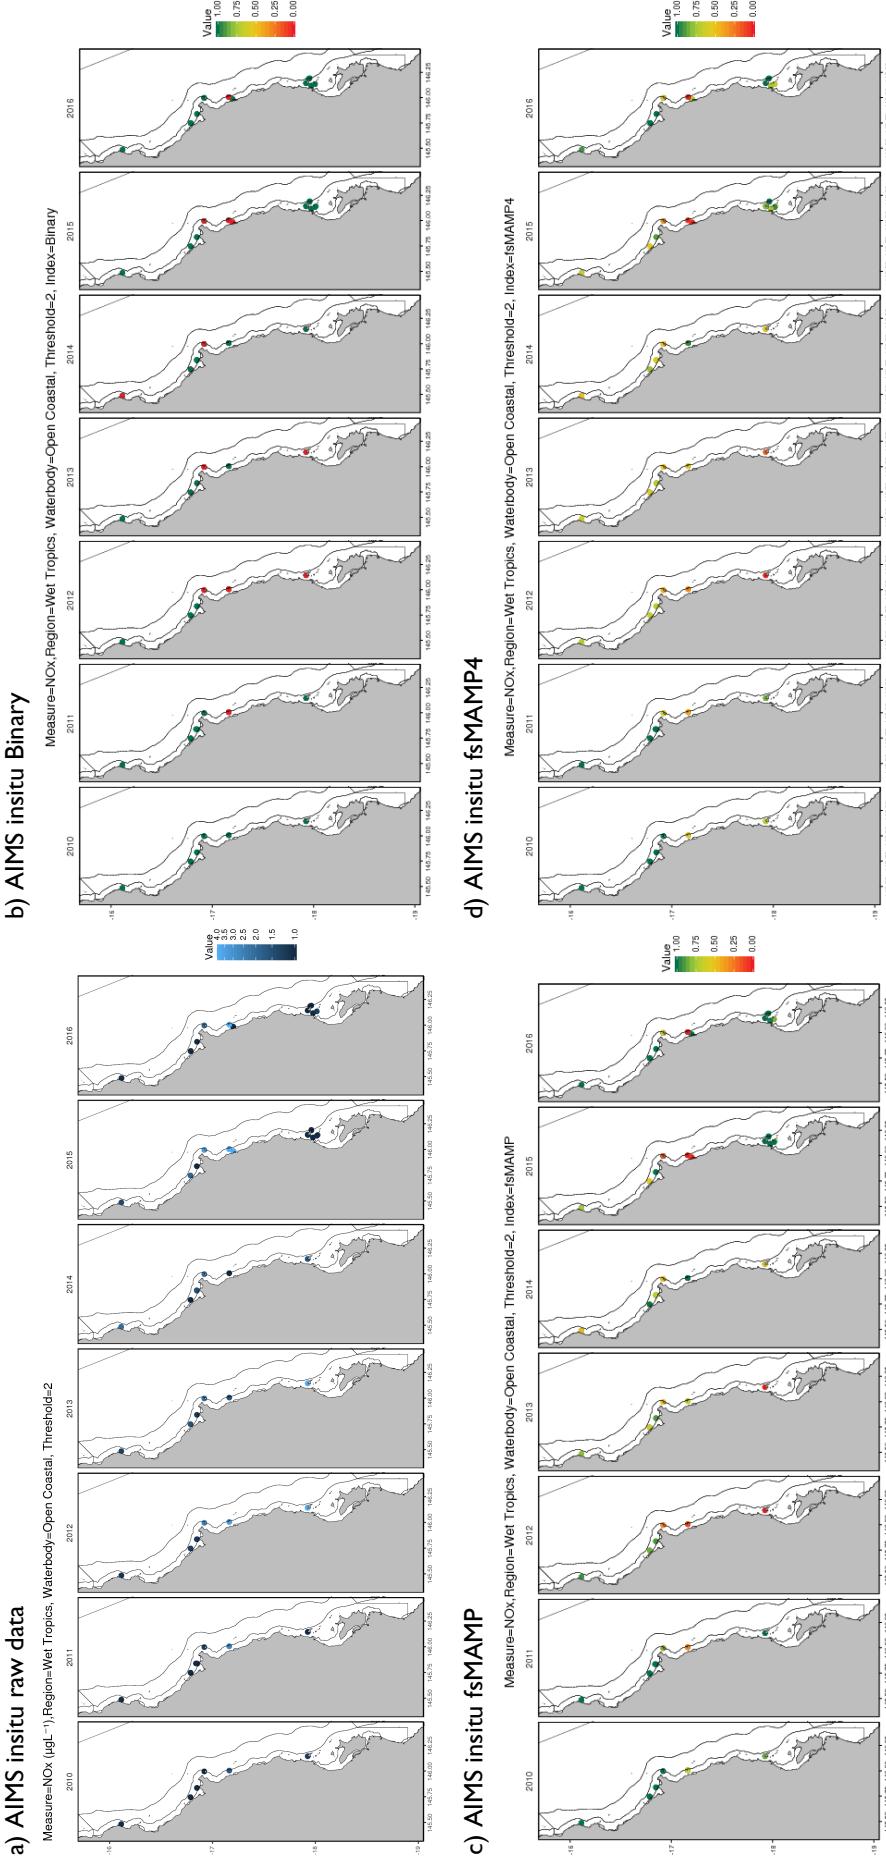

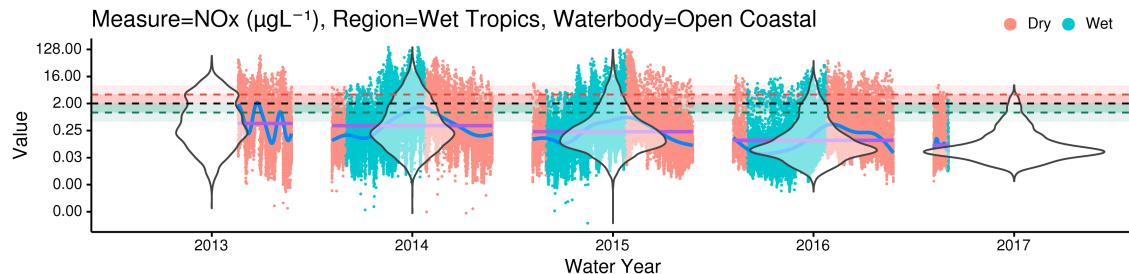

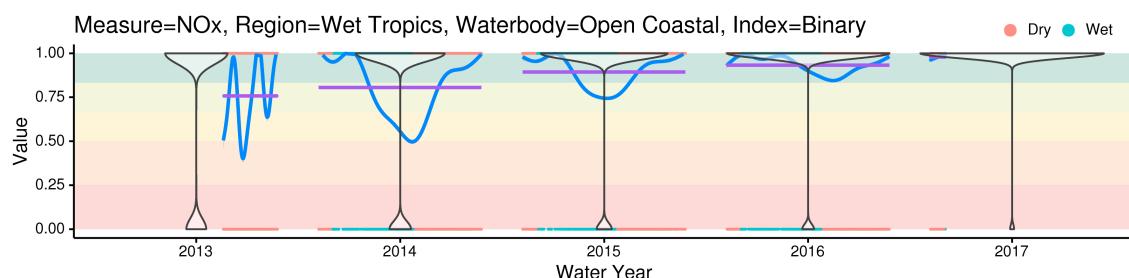

Figure C116: Spatial distribution of AIMS in situ NO_x a) samples and associated b) Binary, c) fsMAMP and d) fsMAMMP4 index formulations for the Wet Tropics Open Coastal zone. Color bars scaled to half (green) and twice (red) threshold value for raw data and 1 (green) and 0 (red) for Binary, fsMAMP and fsMAMMP4.
